THE COLOR ATLAS OF FAMILY MEDICINE

NOTICE

Medicine is an ever-changing science. As new research and clinical experience broaden our knowledge, changes in treatment and drug therapy are required. The authors and the publisher of this work have checked with sources believed to be reliable in their efforts to provide information that is complete and generally in accord with the standards accepted at the time of publication. However, in view of the possibility of human error or changes in medical sciences, neither the authors nor the publisher nor any other party who has been involved in the preparation or publication of this work warrants that the information contained herein is in every respect accurate or complete, and they disclaim all responsibility for any errors or omissions or for the results obtained from use of the information contained in this work. Readers are encouraged to confirm the information contained herein with other sources. For example and in particular, readers are advised to check the product information sheet included in the package of each drug they plan to administer to be certain that the information contained in this work is accurate and that changes have not been made in the recommended dose or in the contraindications for administration. This recommendation is of particular importance in connection with new or infrequently used drugs.

THE COLOR ATLAS OF FAMILY MEDICINE

Second Edition

EDITORS

Richard P. Usatine, MD

Professor of Family and Community Medicine
Professor of Dermatology and Cutaneous Surgery
Assistant Director, Medical Humanities Education
University of Texas Health Science Center at San Antonio
Medical Director, Skin Clinic, University Health System
San Antonio, Texas

Mindy A. Smith, MD

Clinical Professor, Department of Family Medicine
Michigan State University
East Lansing, MI
Deputy Editor, Essential Evidence Plus
Associate Medical Editor, *FP Essentials*

E.J. Mayeaux, Jr., MD

Professor of Family Medicine
Professor of Obstetrics and Gynecology
Family Medicine Residency Program Director and Vice-Chair
Louisiana State University Health Sciences Center
Shreveport, Louisiana

Heidi S. Chumley, MD

Associate Professor, Family Medicine
University of Kansas School of Medicine
Associate Vice Chancellor, Educational Resources and Interprofessional Education
University of Kansas Medical Center
Kansas City, Kansas

This limitation of liability shall apply to any claim or cause whatsoever whether such claim or cause arises in contract, tort or otherwise.

DEDICATION

To our patients who unselfishly agreed to let us display their diseases and afflictions to the world to enhance the study and practice of medicine. We are honored by this trust. We have learned much from our patients as they continue to help us teach the next generation of health care providers.

Sincerely,

Richard P. Usatine, MD

Mindy Ann Smith, MD

PART 1

LEARNING WITH IMAGES AND DIGITAL PHOTOGRAPHY

1 An Atlas to Enhance Patient Care, Learning, and Teaching	2
---	---

PART 2

THE ESSENCE OF FAMILY MEDICINE

2 Doctor—Patient Relationship	8
3 Family Planning	12
4 Pregnancy and Birth	17
5 End of Life	25
6 Social Justice	37
7 Global Health	53

PART 3

PHYSICAL AND SEXUAL ABUSE

8 Child Physical Abuse	82
9 Child Sexual Abuse	89
10 Intimate Partner Violence	95
11 Adult Sexual Assault	102

PART 4

OPHTHALMOLOGY

12 Pterygium	110
13 Hordeolum and Chalazion	114
14 Scleral and Conjunctival Pigmentation	118
15 Corneal Foreign Body and Corneal Abrasion	122
16 Conjunctivitis	126
17 Scleritis and Episcleritis	131
18 Uveitis and Iritis	135
19 Glaucoma	139
20 Diabetic Retinopathy	143
21 Hypertensive Retinopathy	147
22 Papilledema	151
23 Age-Related Macular Degeneration	155
24 Eye Trauma—Hyphema	159
25 Differential Diagnosis of the Red Eye	163

PART 5

EAR, NOSE, AND THROAT

Section 1: Ear

26 Otitis Media: Acute Otitis and Otitis Media with Effusion	170
27 Otitis Externa	180

28 Ear: Foreign Body	185
29 Chondrodermatitis Nodularis Helicis and Preauricular Tags	189

Section 2: Nose and Sinus

30 Nasal Polyps	193
31 Sinusitis	197

Section 3: Mouth and Throat

32 Angular Cheilitis	203
33 Torus Palatinus	206
34 Scarlet Fever and Strawberry Tongue	208
35 Pharyngitis	213
36 The Larynx (Hoarseness)	220

PART 6

ORAL HEALTH

37 Black Hairy Tongue	228
38 Geographic Tongue	232
39 Gingivitis and Periodontal Disease	236
40 Gingival Overgrowth	240
41 Aphthous Ulcer	244
42 Leukoplakia	249
43 Oropharyngeal Cancer	253
44 Early Childhood Caries	257
45 Adult Dental Caries	262

PART 7

THE HEART AND CIRCULATION

Section 1: Central

46 Coronary Artery Disease	268
47 Hypertension	272
48 Heart Failure	277
49 Pericardial Effusion	281
50 Bacterial Endocarditis	287

Section 2: Peripheral

51 Clubbing	292
52 Venous Insufficiency	295

PART 8

THE LUNGS

53 Pneumonia	300
54 Tuberculosis	310
55 Asthma	320
56 Chronic Obstructive Pulmonary Disease	334
57 Pulmonary Embolus	345
58 Lung Cancer	355

PART 9

GASTROINTESTINAL

59	Peptic Ulcer Disease	366
60	Gastric Cancer	371
61	Liver Disease	377
62	Gallstones	386
63	Colon Polyps	393
64	Colon Cancer	399
65	Inflammatory Bowel Disease	405
66	Hemorrhoids	414

PART 10

GENITOURINARY

67	Urinary Sediment	420
68	Kidney Stones	425
69	Hydronephrosis	430
70	Polycystic Kidneys	436
71	Renal Cell Carcinoma	441
72	Bladder Cancer	448
73	Prostate Cancer	453

PART 11

WOMEN'S HEALTH

Section 1: Pregnancy

74	Skin Findings in Pregnancy	462
75	Pruritic Urticarial Papules and Plaques of Pregnancy	467
76	Pemphigoid Gestationis	471
77	First Trimester Obstetrical Ultrasound	475
78	Second Trimester Obstetrical Ultrasound	478
79	Third Trimester Obstetric Ultrasound	482

Section 2: Vaginitis and Cervicitis

80	Overview of Vaginitis	485
81	Atrophic Vaginitis	489
82	Bacterial Vaginosis	494
83	Candida Vulvovaginitis	499
84	Trichomonas Vaginitis	504
85	Chlamydia Cervicitis	509

Section 3: Vulva

86	Paget Disease of the External Genitalia	514
87	Vulvar Intraepithelial Neoplasia	519

Section 4: Colposcopy

88	Colposcopy—Normal and Noncancerous Findings	525
89	Colposcopy of Low-Grade Lesions	530
90	Colposcopy of High-Grade Lesions	535
91	Colposcopy of Cervical Cancer	541

Section 5: Breast

92	Breast Abscess and Mastitis	546
93	Breast Cancer	551
94	Paget Disease of the Breast	557

PART 12

MUSCULOSKELETAL PROBLEMS

95	Arthritis Overview	562
96	Osteoarthritis	569
97	Rheumatoid Arthritis	575
98	Ankylosing Spondylitis	580
99	Back Pain	585
100	Gout	590
101	Olecranon Bursitis	596
102	Clavicular Fracture	601
103	Distal Radius Fracture	605
104	Metatarsal Fracture	611
105	Hip Fracture	615
106	The Knee	619
107	Dupuytren Disease	625

PART 13

DERMATOLOGY

Section 1: Childhood Dermatology

108	Normal Skin Changes	630
109	Childhood Hemangiomas and Vascular Malformations	636
110	Pustular Diseases of Childhood	642
111	Diaper Rash and Perianal Dermatitis	646

Section 2: Acneiform Disorders

112	Acne Vulgaris	651
113	Rosacea	659
114	Pseudofolliculitis and Acne Keloidalis Nuchae	665
115	Hidradenitis Suppurativa	671

Section 3: Bacterial

116	Impetigo	676
117	Folliculitis	680
118	Pitted Keratolysis	686
119	Erythrasma	689
120	Cellulitis	693
121	Abscess	698
122	Necrotizing Fasciitis	702

Section 4: Viral

123	Chickenpox	707
124	Zoster	712
125	Zoster Ophthalmicus	718
126	Measles	723
127	Fifth Disease	728

128 Hand, Foot, and Mouth Disease	732	169 Cutaneous Horn	985
129 Herpes Simplex	735	Section 12: Skin Cancer	
130 Molluscum Contagiosum	743	170 Basal Cell Carcinoma	989
131 Common Warts	749	171 Squamous Cell Carcinoma	999
132 Flat Warts	755	172 Melanoma	1008
133 Genital Warts	759	Section 13: Infiltrative Immunologic	
134 Plantar Warts	766	173 Granuloma Annulare	1022
Section 5: Fungal		174 Pyoderma Gangrenosum	1028
135 Fungal Overview	771	175 Sarcoidosis	1035
136 Candidiasis	777	176 Cutaneous T-Cell Lymphoma	1042
137 Tinea Capitis	782	Section 14: Hypersensitivity Syndromes	
138 Tinea Corporis	788	177 Erythema Multiforme, Stevens-Johnson Syndrome, and Toxic Epidermal Necrolysis	1049
139 Tinea Cruris	795	178 Erythema Nodosum	1056
140 Tinea Pedis	799	179 Vasculitis	1062
141 Tinea Versicolor	805	Section 15: Connective Tissue Disease	
Section 6: Infestations		180 Lupus: Systemic and Cutaneous	1070
142 Lice	809	181 Dermatomyositis	1079
143 Scabies	815	182 Scleroderma and Morphea	1089
144 Cutaneous Larva Migrans	823	Section 16: Bullous Disease	
Section 7: Dermatitis/Allergic		183 Overview of Bullous Diseases	1097
145 Atopic Dermatitis	826	184 Bullous Pemphigoid	1104
146 Contact Dermatitis	834	185 Pemphigus	1109
147 Hand Eczema	843	186 Other Bullous Diseases	1119
148 Nummular Eczema	851	Section 17: Hair and Nail Conditions	
149 Self-Inflicted Dermatoses	856	187 Alopecia Areata	1128
150 Urticaria and Angioedema	863	188 Traction Alopecia and Trichotillomania	1133
Section 8: Papulosquamous Conditions		189 Scarring Alopecia	1138
151 Seborrheic Dermatitis	871	190 Normal Nail Variants	1145
152 Psoriasis	878	191 Pigmented Nail Disorders	1151
153 Pityriasis Rosea	896	192 Ingrown Toenail	1156
154 Lichen Planus	901	193 Onychomycosis	1160
155 Reactive Arthritis	910	194 Paronychia	1166
156 Erythroderma	915	195 Psoriatic Nails	1170
Section 9: Benign Neoplasms		196 Subungual Hematoma	1175
157 Skin Tag	922	Section 18: Pigmentary and Light-Related Conditions	
158 Seborrheic Keratosis	926	197 Melasma	1179
159 Sebaceous Hyperplasia	931	198 Vitiligo and Hypopigmentation	1184
160 Dermatofibroma	935	199 Photosensitivity	1191
161 Pyogenic Granuloma	940	200 Erythema Ab Igne	1198
Section 10: Nevi		Section 19: Vascular	
162 Benign Nevi	945	201 Acquired Vascular Skin Lesions	1203
163 Congenital Nevi	953	202 Hereditary and Congenital Vascular Lesions	1207
164 Epidermal Nevus and Nevus Sebaceous	958	Section 20: Other Skin Disorders	
165 Dysplastic Nevus	963	203 Cutaneous Drug Reactions	1211
Section 11: Pre Cancer/Early Cancer		204 Keloids	1224
166 Actinic Keratosis and Bowen Disease	969	205 Genodermatoses	1229
167 Keratoacanthoma	977	206 Erythema Annulare Centrifugum	1236
168 Lentigo Maligna	981		

CONTENTS

Family physicians probably see a wider variety of rashes, eye conditions, foot disorders, lumps and bumps, and undifferentiated problems than any other specialty. In speaking with healthcare providers and medical students over the years, it became clear that a comprehensive atlas that aided in diagnosis using visible signs and internal imaging would be of tremendous value. We have assembled more than 2000 outstanding clinical images for this very purpose, and are proud to present the second edition of the first modern comprehensive atlas of family medicine ever produced. Some photographs will amaze you; all will inform you about the various conditions that befall our patients.

We were gratified by the great response to the first edition. The iPad and smartphone versions were also very well received and are again available for the second edition. Readers sent in a number of suggestions for additions and we have taken those to heart, with extensive new coverage of fundamental conditions.

New in the second edition are:

- New chapters that expand the scope of the book, including chapters on Global Health, Nummular Eczema, Alcoholism, and Tobacco Addiction. Most importantly, we have added chapters on topics that are found in the core curriculum for a Family Medicine Clerkship or a Family Medicine Residency:
 - Hypertension, diabetes, asthma, prostate cancer, arthritis overview, osteoarthritis, back pain, obesity, osteoporosis, and headache.
- The chapter template has been expanded to include more on prevention, prognosis, and risk factors for disease in many of the chapters.

It took a number of people many years to create the first edition of *The Color Atlas of Family Medicine*. For me it was a life work that started with little notebooks I kept in my white coat pocket to take notes during my residency. It then took on color and images as I kept a camera at work and took photographs with my patient’s permission of any interesting clinical finding that I might use to teach medical students and residents the art and science of medicine. I was inspired by many great family physicians, including Dr. Jimmy Hara, who had the most amazing 35-mm slide collection of clinical images. His knowledge of medicine is encyclopedic and I thought that his taking photographs might have something to do with that. Also, I realized that these photographs would greatly enhance my teaching of others. As I began to expand my practice to see more dermatology cases, my photograph collection skyrocketed. Digital photography made it more affordable and practical to take and catalogue many new images.

The Color Atlas of Family Medicine is written for family physicians and all healthcare providers involved in primary care. It can also be invaluable to medical students, residents, internists, pediatricians, and dermatologists. This second edition is coming out just prior to the

release of two new *Color Atlas’s* in our new series:

- *The Color Atlas of Internal Medicine*
- *The Color Atlas of Pediatrics*

The first edition of *The Color Atlas of Family Medicine* is available electronically for iPad, iPhone, iPod touch, all Android devices, Kindle, and on the web through Access Medicine. These electronic versions have allowed healthcare providers to access the images and content rapidly at the point-of-care.

One doctor wrote, “As a teacher and learner in Family Medicine and Dermatology, this atlas is an invaluable resource. Excellent quality pictures look great on the iPad. My patients appreciate seeing pictures of other people with the same medical conditions as theirs. Concise and evidence-based recommendations are just what we need in the busy setting of primary care. It is one of my most frequently referenced books/apps. A must-have for every teacher, learner or practitioner of Family Medicine or primary care.”

The second edition will also have all the same electronic versions with increased functionality.

The second edition of *The Color Atlas of Family Medicine* is for anyone who loves to look at clinical photographs for learning, teaching, and practicing medicine. The first chapter begins with an introduction to learning with images and digital photography. The core of the book focuses on medical conditions organized by anatomic and physiologic systems. Both adult and childhood conditions are included as this book covers healthcare from birth to death. There are special sections devoted to the essence of family medicine, physical/sexual abuse, women’s health, and substance abuse.

The collection of clinical images is supported by evidence-based information that will help the healthcare provider diagnose and manage common medical problems. The text is concisely presented with many easy to access bullets as a quick point of care reference. Each chapter begins with a patient story that ties the photographs to the real life stories of our patients. The photographic legends are also designed to connect the images to the people and their human conditions. Strength of recommendation ratings are cited throughout so that the science of medicine can be blended with the art of medicine for optimal patient care.

We have created 3 special indexes to help you find information and diagnoses quickly and efficiently. The topic index printed on the front inside cover allows for quick access to major topic areas. The regional index for diagnosis can be used when you have an unknown condition and want to search for possible diagnoses by region of the body. Finally, the morphology index is to aid in the diagnosis of conditions which you can describe morphologically but for which the actual diagnosis remains uncertain.

Because knowledge continues to advance after any book is written, use the online resources presented in many of the chapters to keep up with the newest changes in medicine. Care deeply about your patients and enjoy your practice, as it is a privilege to be a healthcare provider and healer.

Strength of Recommendation (SOR)	Definition
A	Recommendation based on consistent and good-quality patient-oriented evidence.*
B	Recommendation based on inconsistent or limited-quality patient-oriented evidence.*
C	Recommendation based on consensus, usual practice, opinion, disease-oriented evidence, or case series for studies of diagnosis, treatment, prevention, or screening.*

*See Appendix A on pages 1447–1450 for further information.

This book could not have been completed without the contributions of many talented physicians, healthcare professionals, and photographers. We received photographs from people who live and work across the globe. Each photograph is labeled and acknowledges the photographer and contributor. Some photographs were previously published in the Photo Rounds column of the *Journal of Family Practice*. For these we thank Frontline Medical Communications, for generously sharing these photographs with our readers. Being the founding editor of this column has given me the opportunity to see a great collection of clinical photographs over the years.

In the year 2000, I began giving every medical student a digital camera as they rotated through the family medicine clerkship at UCLA. We have continued this process at University of Texas Health Sciences Center at San Antonio (UTHSCSA) except now most students have their own digital cameras or smartphones with cameras. Some of their best photographs are incorporated into our book. What could be better than to have our medical students record the clinical images that they see while rotating on family medicine? Not only do the students teach each other using these photographs, but they now will help educate our readers on the vast breadth and scope of family medicine.

There are some people who contributed so many photographs it is appropriate to acknowledge them upfront in the book. Paul Comeau was the professional ophthalmology photographer at UTHSCSA. His beautiful photographs of the external and internal eye make the ophthalmology section of this book so rich and valuable. The dermatology division at UTHSCSA contributed much of their expertise in photography, writing, and reviewing the extensive dermatology section. During the last few years, I was fortunate to work closely with the dermatology faculty and residents and they contributed generously to our book. Dr. Eric Kraus, the program director, gave us many wonderful photographs, especially for the section on bullous diseases. He also gave us open access to the 35-mm slides collected by the Division of Dermatology. Dr. Jeff Meffert also contributed photographs to many chapters. Many dermatology residents wrote chapters and contributed photographs. Dr. Jack Resneck, Sr., from Louisiana, scanned his slides from more than 40 years of practice and gave them to Dr. E.J. Mayeaux, Jr., for use. Dr. Resneck's vast dermatologic experiences add to our atlas.

The UTHSCSA Head and Neck Department contributed many photographs for this book. We especially thank Dr. Frank Miller and Dr. Blake Simpson for their contributions. UTHSCSA pediatrics faculty contributed to our chapters on child abuse and otitis media. We are fortunate to have Dr. Nancy Kellogg contribute her photographs and expertise in caring for abused children to the book. Dr. Dan Stulberg, a family physician from New Mexico, with a passion for photography and dermatology, contributed many photographs throughout our book. Dr. Ellen Eisenberg, an oral pathologist was generous in sharing her vast collection of images with us.

We thank our learners, many of whom coauthored chapters with us. UTHSCSA medical students and residents and fellows from Michigan State University's Primary Care Faculty Development Fellowship program coauthored chapters and contributed photographs with great enthusiasm to the creation of this work. It was a pleasure to mentor these young writers and experience with them the rewards of authorship. This second edition is special because I (Dr. Usatine) had the privilege of mentoring 2 wonderful physicians

in my new "Underserved Dermatology Fellowship" for family physicians. Both of my recent fellows have contributed significantly to this edition. Dr. Jonathan Karnes updated all our skin cancer chapters and contributed his own photos. Dr. Yu Wah wrote our new nummular eczema chapter, contributed photos, and her eye for quality images was indispensable when I was choosing between many possible photos for our book. Working closely with such brilliant and caring doctors in our Skin Clinic and free outreach clinics allowed me to learn from them while doing my best to advance their academic and humanistic careers.

We want to thank Dr. Kelly Green for reviewing and improving the ophthalmology section. She not only went over each chapter word by word, but she also made sure that our photographs were properly described and labeled. Dr. Green was a former student of mine and I am proud to see the wonderful ophthalmologist that she has become.

Of course, we would have no book without the talented writing and editing of my coeditors, Drs. Mindy A. Smith, E.J. Mayeaux, and Heidi Chumley. They each bring years of clinical and educational experience to the writing of the *Atlas*. Dr. Mayeaux contributed many of his own photographs, especially in women's healthcare, to our *Atlas*. I value their friendship along with what they contributed to this new edition.

Most of all we need to thank our patients who generously gave their permission for their photographs to be taken and published in this book. While some photos are not recognizable, we have many photos of the full face that are very recognizable and were generously given to us by our patients with full written permission to be published as is. For photographs that were taken decades ago in which written consents were no longer available, we have used bars across the eyes to make the photos less recognizable—verbal consent was always obtained for these images.

The last section of this book is dedicated to understanding substance abuse (chemical dependency) and its treatment. This could not have been done without the generous contributions of the dedicated staff and the women residents at Alpha Home, a nonprofit alcohol and drug treatment program in San Antonio. The medical students and faculty (including Dr. Usatine every Monday evening) from UTHSCSA spend 2 to 3 evenings a week providing free healthcare to these women who are bravely facing their addictions and fighting to stay sober 1 day at a time. Their pictures have been generously added to our book with their permission.

I (Dr. Richard Usatine) thank my family for giving me the support to see this book through. It has taken much time from my family life and my family has supported me through the long nights and weekends it takes to write a book while continuing to practice and teach medicine. I am fortunate to have a loving wife and 2 beautiful children and one very cute grandson who add meaning to my life and allowed me to work hard on the creation of this *Color Atlas*.

Dr. Mindy Smith adds, "I thank my husband, Gary, and daughter, Jenny, for their support and willingness to listen when I struggle with phrasing and wording in my writing and editing. I also thank several colleagues who have helped me to establish myself as an editor and supported my continued growth in this field—Drs. Barry Weiss, Mark Ebell, Richard Usatine, Suzanne Sorkin, and Leslie Shimp."

Dr. E.J. Mayeaux adds, "I would like to thank my wife and son for understanding the many hours of work and computer time in my meager efforts to leave the world a better place. I would also thank my family for teaching me to see the world as a beautiful, joyous,

photogenic, beckoning, fascinating place. I hope this book helps each reader see the world this way.”

Dr. Heidi Chumley adds, “I want to thank my husband, John Delzell, who has brought love and peace to my often chaotic life, and my children, Cullen, Sierra, David, Selene, and Jack, who give me joy and provide the incentive to stay on task. Each one, in turn, has cheerfully pitched in to help a grumpy and tired mom who stayed up most of the night working on one of many chapters. I have been very blessed.”

Finally, we all thank James Shanahan and Karen Edmonson from McGraw-Hill for believing in this project and never giving up as our book grew larger and more comprehensive over time. Jim Shanahan’s wisdom and support have been particularly valuable as our first edition became an early iPhone app and is developing into two new color atlases for pediatricians and internists. Jim not only helped us keep our eye on the puck but helped us to keep our eye on where the puck was going.

PART 1

LEARNING WITH IMAGES AND DIGITAL PHOTOGRAPHY

Strength of Recommendation (SOR)	Definition
A	Recommendation based on consistent and good-quality patient-oriented evidence.*
B	Recommendation based on inconsistent or limited-quality patient-oriented evidence.*
C	Recommendation based on consensus, usual practice, opinion, disease-oriented evidence, or case series for studies of diagnosis, treatment, prevention, or screening.*

*See Appendix A on pages 1447–1450 for further information.

1 AN ATLAS TO ENHANCE PATIENT CARE, LEARNING, AND TEACHING

Richard P. Usatine, MD

People only see what they are prepared to see.

—Ralph Waldo Emerson

Whether you are viewing **Figure 1-1** in a book, in an aquarium, or in the sea, you immediately recognize the image as a fish. Those of you who are more schooled in the classification of fish might recognize that this is an angelfish with the tail resembling the head of the angel and the posterior fins representing the wings. If you are truly prepared to see this fish in all its splendor, you would see the blue circle above its eye as the crown of the queen angelfish.

Making a diagnosis in medicine often involves the kind of pattern recognition needed to identify a queen angelfish. This is much the same as recognizing a beautiful bird or the painting of a favorite artist. If you are prepared to look for the clues that lead to the identification (diagnosis), you will see what needs to be seen. How can we be best prepared to see these clues? There is nothing more valuable than seeing an image or a patient who has the condition in question at least once before you encounter it on your own. The memory of a powerful visual image can become hard wired into your brain for ready recall.

In medicine it also helps to know where and how to look to find the clues you may need when the diagnosis cannot be made at a single glance. For example, a patient with inverse psoriasis may present with a rash under the breast that has been repeatedly and unsuccessfully treated with antifungal agents for candidiasis or tinea (**Figures 1-2** and **1-3**). The prepared clinician knows that not all erythematous plaques under the breast are fungal and looks for clues such as nail changes (**Figures 1-2** and **1-4**) or scaling erythematous plaques around the elbows, knees, or umbilicus (**Figure 1-3**). Knowing where to look and what to look for is how an experienced clinician makes the diagnosis of psoriasis.

USING OUR SENSES

As physicians we collect clinical data through sight, sound, touch, and smell. Although physicians in the past used taste to collect data, such as tasting the sweet urine of a patient with diabetes, this sense is rarely, if ever, used in modern medicine. We listen to heart sounds, lung sounds, bruits, and percussion notes to collect information for diagnoses. We touch our patients to feel lumps, bumps, thrills, and masses. We occasionally use smell for diagnosis. Unfortunately, the smells of disease are rarely pleasant. Even the fruity odors of *Pseudomonas* are not like the sweet fruits of a farmers' market. Of course, we also use the patient's history, laboratory data, and more advanced imaging techniques to diagnose and manage patients' illnesses.

FIGURE 1-1 Queen angelfish (*Holacanthus ciliaris*). (Courtesy of Sam Thekkethil. <http://www.flickr.com/photos/natureloving/>)

FIGURE 1-2 Inverse psoriasis under the breast that might appear to be a fungal infection to the untrained eye. Note the splinter hemorrhages in the nail of the third digit that provide a clue that the patient has psoriasis. (Courtesy of Richard P. Usatine, MD.)

OUR NEW EDITION DELIVERS MORE IMAGES AND INFORMATION

It was our belief in the value of visual imagery that led to the development of the first edition of *The Color Atlas of Family Medicine*. We delivered more than 1500 images to doctors around the world, first as a large color textbook and then as an interactive electronic application for easy use on the iPhone, iPod touch, iPad, and all Android devices. Our images were so valuable for learning and practicing medicine that they were requested for use and then incorporated into other primary care and specialty textbooks, websites, CME presentations, and test-preparation services. Now it is our pleasure to bring you our second edition of *The Color Atlas of Family Medicine* with more than 2000 clinical images.

We also have added many new chapters on such important topics as diabetes, hypertension, headache, osteoporosis, alcoholism, tobacco addiction, and global health. Although these topics were covered to some extent in the first edition, we decided to create these new chapters so that the text and images would become a comprehensive resource for the full range of family medicine. Electronic applications for the new color atlas will be available in all major platforms at the same time that the new book will be released.

EXPANDING OUR INTERNAL IMAGE BANKS

The larger our saved image bank in our brain, the better clinicians and diagnosticians we can become. The expert clinician has a large image bank stored in memory to call on for rapid pattern recognition. Our image banks begin to develop in medical school when we view pictures in lectures and textbooks. We then begin to develop our own clinical image bank by our clinical experiences. Our references are printed color atlases and those color atlases available on the Internet and electronically.

Studying and learning the patterns from any atlas can enhance your expertise by enlarging the image bank stored in your memory. An atlas takes the clinical experiences of clinicians over decades and gives it to you as a single reference. We offer you, for the first time in the United States, a modern comprehensive family medicine color atlas, which includes areas such as oral health, dermatology, podiatry, and the eye.

USING IMAGES TO MAKE A DIAGNOSIS

We all see visible clinical findings on patients that we do not recognize. When this happens, open this book and look for a close match. Use the Appendix, Index, or Table of Contents to direct you to the section with the highest yield photos. If you find a direct match, you may have found the diagnosis. Read the text and see if the history and physical examination match your patient. Perform or order tests to confirm the diagnosis, if needed.

If you cannot find the image in our book try the Internet and the Google search engine. Try a Google image search and follow the leads. Of course this is easiest to do if you have a good differential diagnosis and want to confirm your impression. If you don't have a

FIGURE 1-3 The patient in **Figure 1-2** with inverse psoriasis had a typical psoriatic plaque in the umbilicus. This was the only other area involved besides the breasts and the nails but easily could have been missed without the knowledge of where to look for the clues needed to make the diagnosis. (Courtesy of Richard P. Usatine, MD.)

FIGURE 1-4 When the diagnosis of psoriasis is being considered, look at the nails for pitting or other nail changes such as splinter hemorrhages, onycholysis, or oil spots. This is a good example of nail pitting in a patient with psoriasis. (Courtesy of Richard P. Usatine, MD.)

diagnosis in mind, you may try putting in descriptive words and look for an image that matches what you are seeing. If the Google image search does not work, try a Web search and look at the links for other clues.

Finally, there are dedicated atlases on the Internet for organ systems that can help you find the needed image. Most of these atlases have their own search engines, which can help direct you to the right diagnosis.

Table 1-1 lists some of the best resources currently available online.

USING IMAGES TO BUILD TRUST IN THE PATIENT–PHYSICIAN RELATIONSHIP

If you are seeing a patient with a mysterious illness that remains undiagnosed and you figure out the diagnosis, you can often bridge the issues of mistrust and anxiety by showing the patient the picture of another person with the diagnosis. Use our atlas for that purpose and supplement it with the Internet. This is especially important for a patient who has gone undiagnosed or misdiagnosed for some time. “Seeing is believing” for many patients. Ask first if they would want to see some pictures of other persons with a similar condition; most will be very interested. The patient can see the similarities between their condition and the other images and feel reassured that your diagnosis is correct. Write down the name of the diagnosis for your patient and use your patient education skills.

Do be careful when searching for images on the Web in front of patients. Sometimes what pops up is not “pretty” (or, for that matter, G or PG rated). I turn the screen away from the patients before initiating the search and then censor what I will show them.

If you teach, model this behavior in front of your students. Show them how reference books and the Internet at the point of care can help with the care of patients.

TAKING YOUR OWN PHOTOGRAPHS

Images taken by you with your own camera of your own patients complete with their own stories are more likely to be retained and retrievable in your memory because they have a context and a story

to go with them. We encourage our readers to use a digital camera (within a smartphone or a stand-alone camera) and consider taking your own photos. Of course, always ask permission before taking any photograph of a patient. Explain how the photographs can be used to teach other doctors and to create a record of the patient’s condition at this point in time. If the photograph will be identifiable, ask for written consent; for patients younger than age 18 years, ask the parent to sign. Store the photos in a manner that avoids any Health Insurance Portability and Accountability Act (HIPAA) privacy violations, such as on a secure server or on your own computer with password protection and data encryption. These photographs can directly benefit the patient when, for example, following nevi for changes.

Digital photography is a wonderful method for practicing, teaching, and learning medicine. You can show patients pictures of conditions on parts of their bodies that they could not see without multiple mirrors and some unusual body contortions. You can also use the zoom view feature on the camera or smartphone to view or show a segment of the image in greater detail. Children generally love to have their photos taken and will be delighted to see themselves on the screen of your camera.

The advent of digital photography makes the recording of photographic images less expensive, easier to do, and easier to maintain. Digital photography also gives you immediate feedback and a sense of immediate gratification. No longer do you have to wait for a roll of film to be completed and processed before finding out the results of your photography. Not only does this give you immediate gratification to see your image displayed instantaneously in the camera, but also alerts you to poor-quality photographs that can be retaken while the patient is still in the office. This speeds up the learning curve of the beginning photographer in a way that could not happen with film photography.

OUR GOALS

Many of the images in this atlas are from my collected works over the past 27 years of my practice in family medicine. My patients

have generously allowed me to photograph them so that their photographs would help the physicians and patients of the future. To these photos, we have added images that represent decades of experiences by other family physicians and specialists. Family physicians who have submitted their images to Photo Rounds in the *Journal of Family Practice* are also sharing their photos with you. Finally, 12 years of providing students with cameras during their Family Medicine clerkships at the University of California at Los Angeles (UCLA) and the University of Texas Health Sciences Center at San

Antonio (UTHSCSA) have allowed our students to add their experiences to our atlas.

It is the goal of this atlas to provide you with a wide range of images of common and uncommon conditions and provide you with the knowledge you need to make the diagnosis and initiate treatment. We want to help you be the best diagnostician you can be. We may aspire to be a clinician like Sir William Osler and have the detective acumen of Sherlock Holmes. The images collected for this atlas can help move you in that direction by making you prepared to see what you need to see.

THE ESSENCE OF FAMILY MEDICINE

Strength of Recommendation (SOR)	Definition
A	Recommendation based on consistent and good-quality patient-oriented evidence.*
B	Recommendation based on inconsistent or limited-quality patient-oriented evidence.*
C	Recommendation based on consensus, usual practice, opinion, disease-oriented evidence, or case series for studies of diagnosis, treatment, prevention, or screening.*

*See Appendix A on pages 1447–1450 for further information.

2 DOCTOR—PATIENT RELATIONSHIP

Mindy A. Smith, MD, MS

Humor is one way through which patients and physicians relate to each other on a human level. Even politics is not off-limits in the doctor–patient relationship.

PATIENT STORY

Patient stories, particularly if we listen attentively and nonjudgmentally, provide us with a window into their lives and experiences. These stories help us to know our patients in powerful ways, and that knowledge about the patient, as someone special, provides the context, meaning, and clues about their symptoms and illnesses that can lead to healing. At our best, we serve as witness to their struggles and triumphs, supporter of their efforts to change and grow, and guide through the medical maze of diagnostic and therapeutic options. Sometimes, their stories become our own stories—those patients who we will never forget because their stories have changed our lives and the way we practice medicine (**Figure 2-1**).

WHAT PATIENTS WANT FROM THEIR PHYSICIAN

As part of the future of family medicine (FFM) initiative, telephone interviews of the general public (N = 1031) were conducted in 2002.¹ Most patients strongly agreed that they wanted to take an active role in their healthcare (82% and 91%, patients with family physicians and patients with general internists, respectively), they wanted their physicians to treat a wide variety of medical problems but refer to a specialist when necessary (88% and 84%), and they wanted a physician who looks at the whole person—emotional, psychological, and physical (73% and 74%). In addition, of 39 possible attributes of physicians, most patients (68% to 97% stated extremely or very important) viewed the following as the most important attributes/services that drive overall satisfaction with their physician:

- Does not judge; understands and supports.
- Always honest, direct.
- Acts as partner in maintaining health.
- Treats both serious and nonserious conditions.
- Attends to emotional and physical health.
- Listens to me.
- Encourages healthier lifestyle.
- Tries to get to know me.
- Can help with any problem.
- Someone I can stay with as I get older.

FIGURE 2-1 Dr. Jim Legler caring for a young girl in a free clinic within a transitional housing village for homeless families. He is a family physician who volunteers every week to care for the 40 families working their way out of homelessness. He had been caring for Kimberly and her family for many months at the time this photograph was taken. Dr. Legler serves as a role model for students interested in primary care of the underserved. He is known for his kindness and compassion to all his patients.

WHAT PHYSICIANS WANT FROM AND FOR PATIENTS

Although the types and intensity of relationships with patients differ, our positive and negative experiences with patients shape us as clinicians, influence us in our personal relationships, and shape the character of our practices. Arthur Kleinman, in his prologue to *Patients and Doctors: Life-Changing Stories from Primary Care*, wrote, “We all seem to want (or demand) experiences that matter, but maybe what is foremost is that we want experiences in which *we* matter.” There is perhaps no greater satisfaction than the beliefs that what we do and who we are matters to those we care for in both our personal and professional lives.² A positive relationship with a patient is one of mutual growth. This concept of doctor–patient reciprocity is not new and can be found in the writings of Erasmus, more than 500 years ago, arising from a classical conception of friendship.³

As clinicians we want patients to be healthier and improved in some meaningful way after our encounter with them. Meaningful elements common to healing practices across cultures include:⁴

- Providing a meaningful explanation for the sickness.
- Expressing care and concern.
- Offering the possibility of mastery and control over the illness or its symptoms.

Family physicians (N = 300) who were interviewed as part of the FFM initiative stated that the following things completely captured the essence of what they found as most satisfying about being a family physician:¹

- The deep relationships developed with patients over the years (54%).
- The variety—no day is ever the same (54%).
- Offers me a strong sense of purpose because I can make a real difference in people’s lives (48%).
- Don’t spend their days taking care of illness, but take care of the whole patient (**Figure 2-2**) (46%).

LEARNING FROM PATIENTS

To learn from patients, clinicians must do the following:

- Move outside of their worldview and accept the patient’s point of view and belief system.
- Let go of stereotypes, biases, and dogma.
- Use active empathic listening, see the patient in context, and adopt reflective and reflexive practices.⁵
- Emphasize patient dignity and control within a supportive team, which may include family, friends, aides, and community resources.
- Graciously accept differences of opinion or patient refusal without abandoning the patient.
- Look at each patient encounter as a cross-cultural event.⁴ Western medical training acculturates clinicians into a world seen in large part as one of problems and solutions; this is often at odds with patients’ need to find meaning in the illness episode, be heard and acknowledged, and learn to live a quality life with chronic illness.

FIGURE 2-2 Dr. Alan Blum is a family physician who has been doing sketches of his patients for decades now. When he presents his drawings of his patients, he reads his poetic stories that go with the drawings. Some of his drawings have been published in *JAMA*. Here is the poem that goes with this man’s story:

“Gov’mnt gave me a chance
to get a hearin’ aid for free.
But when I went to th’ doctor,
he say,
‘Well, cap’n,
there gonna be a lot o’ things
you don’t want to hear!”

BENEFITS OF A GOOD DOCTOR–PATIENT RELATIONSHIP

Beyond the benefit of enhancing the medical experience for both clinicians and patients, data that support developing a good doctor–patient relationship include the following:

- Patients who are satisfied with their physicians are three times more likely to follow a prescribed medical regimen.⁶
- Patients with diabetes cared for by physicians with high empathy scores (based on the physician’s self-administered Jefferson Scale of Empathy) were significantly more likely to have good control based on hemoglobin A_{1C} than were patients of physicians with low empathy scores (56% and 40%, respectively).⁷
- Patients who reported an established relationship with a primary care provider (PCP) were less likely to currently smoke than those who lacked a PCP relationship (26.5% and 62.3%, respectively).⁸
- There is a direct link between patient satisfaction and the amount of information that physicians provide.^{9,10}
- There is also a strong positive correlation between patient satisfaction, recall, and understanding and physician’s partnership building (e.g., enlisting patient input).¹⁰
- Provision of health information to patients influences patient decision making in important ways.

ESSENTIALS OF GOOD DOCTOR–PATIENT RELATIONSHIP

Although the doctor–patient relationship may be viewed as a contract for providing services, Dr. Candib argues that this view does not fit well with developing a healing relationship that must be based on “unconditional positive regard,” beneficence, caring, and a moral basis of conduct.¹¹ Furthermore, contracts fail to deal with the unpredictable and fail to acknowledge the power inequality between physicians and patients. To counter this power imbalance, Candib emphasizes the need for clinicians to use that power to empower the patient. Following are the requirements of empowerment of patients:¹²

- Recognition of oppression—Acknowledging the patient’s contextual problems (e.g., poverty, race, religion, sexual preference) and the sources of inequality and oppression that contribute to their health status for the purpose of naming and supporting the patient’s reality.
- Expressing empathy—A characteristic of being with the patient that leads to empowerment by confirming the worthiness of the other.
- Respecting the patient as a person (particularly those who are cognitively or otherwise impaired).
- Responding to the changing abilities of the patient—Using flexibility, timing, and a shifting of skills to advance the movement of the patient in a positive stronger direction.

- Using language that increases patient’s power—Solicit and legitimize the patient’s explanations and experience. This may include using questions about what patients want from the encounter, what they think about their problem, what they think the clinician should do about the problem, and what they have tried that has worked for them in the past.
- Taking the patient seriously—This includes respecting the patients’ fears, not trivializing their concerns, and allowing the truth to unfold over time to prevent patient harm or embarrassment.
- Supporting choice and control—Accepting patient priorities, even if health is not the top one, and allowing patients to choose, even if their choice is to relinquish control.
- Eliciting the patient’s story, often over time, to be able to put the illness experience into historical and social context.
- Providing patient education in a context in which the clinician asks what the patient already knows, what they want and need to know, and whether they have any questions. Health educators should discuss risks and benefits of a proposed diagnostic or treatment plan that are meaningful to the patient and provide patients with the tools and information to make their own decisions.

Some patients prefer to delegate authority to the physician to make medical decisions; the challenge then is for the physician to find out the patient’s preferences and values.

Caring is also an essential feature of a good doctor–patient relationship. Caring, as connectedness with a patient, evolves from the relationship. Within the context of this relationship, the clinician makes the patient feel known, pays attention to the meaning that a symptom or illness has in the patient’s life, expresses real feeling (separate from reflecting back the patient’s feelings), and practices devotion (e.g., a willingness at times to do something extra for the patient).¹³ To provide caring to patients, clinicians must take care of themselves.

SKILLS FOR BUILDING GOOD DOCTOR–PATIENT RELATIONSHIPS

- One strategy for improving communication with patients is using the patient-centered interview.¹⁴ This technique focuses on eliciting the patient’s agenda in order to address their concerns more promptly.
- Incorporating the BATHE (Background, Affect, Trouble and Handling of their current situation, and Empathy) method into the standard patient interview was found to increase 8 of 11 measures of patient satisfaction.¹⁵
- Using self-disclosure for the purposes of role modeling and guiding, showing empathy, building trust, and developing a stronger relationship in the context of shared assumptions about the relationship. Self-disclosure, however, must be balanced with the obligation not to take advantage of patients by using such disclosure as an appeal for help or intimacy.¹⁶ In addition, it may be prudent to avoid disclosure of unresolved issues and to avoid repetitiousness (as when disclosure predominates over inquiry).

MAXIMIZING THE EFFECTIVENESS OF PATIENT EDUCATION

Steps for maximizing patient education for behavior change include the following:¹⁷

- Understanding the power of the clinician's expertise as a motivator toward behavior change.
- Being patient centered and patient responsive (e.g., assess readiness to change, patient wishes for autonomy or assistance in decision making).
- Encouraging the patient to choose one or at most two behavior goals at a time.
- Being specific in the advice given.
- Obtaining commitment from the patient for change.
- Using multiple educational strategies, often over time and from a team of providers.
- Using social support when possible.
- Assuring appropriate follow-up.

Some guidance can be found in the literature for discussing clinical evidence with patients in the process of making medical decisions. Despite lack of clinical outcomes from this research, authors of a systematic review found the following:¹⁸

- Methods for communicating clinical evidence to patients include nonquantitative general terms, numerical translation of clinical evidence, graphical representations, and decision-making aids.
- Focus-group data suggested that clinicians present options and/or equipoise before asking patients about preferred decision-making roles or formats for information.
- Absolute risk reduction is preferred.
- The order of information presented and time frame of outcomes can bias patient understanding.
- Limited evidence supports use of human stick figure graphics or faces for single probabilities and vertical bar graphs for comparative information.
- Less-educated and older patients preferred proportions to percentages and did not appreciate confidence intervals.

3 FAMILY PLANNING

E.J. Mayeaux Jr., MD
James C. Barrow, MD, FACOG

PATIENT STORY

Your patient is a 25-year-old married woman who wants to postpone having children for another 2 years while she finishes graduate school. She and her husband are currently using condoms, but would like to change to something different. She is in good health and does not smoke. It is now your opportunity to discuss with her all the methods available to prevent pregnancy. First, you determine what she knows about the methods and if she has any preferences. She tells you that she is specifically interested in either the *hormonal vaginal ring* (NuvaRing) (Figure 3-1) or the newest *intrauterine device* that releases a hormone (Figure 3-2). Then you participate in shared decision making as she comes up with the method that best fits her lifestyle and health issues.

INTRODUCTION

Contraception is like many other treatments in medicine. Each method has its risks and benefits. Each method has its barriers to use, such as compliance, cost, and social stigmas. By educating patients appropriately and letting them know beforehand of potential side effects, we can greatly increase compliance and satisfaction.

EPIDEMIOLOGY

- Approximately one-half of pregnancies in the United States are unintended.¹ Approximately one-half of these occurred in women using reversible contraception.²
- The most commonly used contraceptive methods in the United States are oral contraceptive pills (OCPs), male condoms, and female sterilization.³
- Long-acting reversible forms of contraception are increasingly popular. Encouraging these methods may help lower the unintended pregnancy rate. Gaps or discontinuation of use of short-acting methods lead to unintended pregnancy.⁴
- Newer contraceptives often have improved side-effect profiles or have more convenient delivery systems that may not require daily patient adherence. Having a wide range of contraceptive options helps patients find a method that will work best for them.
- This chapter focuses on contraceptive methods available in the United States and the considerations one must address when counseling patients on their choice of method.

CONSIDERATIONS

- No contraception method is perfect. Each individual or couple must balance the advantages and disadvantages of each method and decide which offers the best choice. As the physician, one must help

FIGURE 3-1 NuvaRing is a combined hormonal intravaginal contraceptive ring. The flexible material of the ring allows for easy insertion and removal. Note the size in comparison to a quarter. (Courtesy of Richard P. Usatine, MD.)

TABLE 3-1 Contraceptive Options Available in the United States in 2012

Method	Unintended Pregnancies with 1 Year of Use (%)		Noncontraceptive Benefits	Use with Breastfeeding
	Typical Use	Theoretical		
None	85	85	—	—
Spermicide	29	18	None	Yes
Withdrawal	27	4	None	Yes
Periodic abstinence (fertility awareness)	25	3–5	None	Yes
Diaphragm with spermicide	16	6	None	Yes
Female condom	21	5	Prevents STDs	Yes
Male condom	15	2	Prevents STDs	Yes
OCPs—combined and progestin-only	8	0.3	Regulation of menstrual cycle and dysmenorrhea, possible decrease in ovarian and endometrial cancer risk, decrease acne	No
Contraceptive patch	8	0.3	Same as OCPs	No
Vaginal ring	8	0.3	Same as OCPs	No
Depo-Provera	3	0.3	Same as OCPs	Yes
Copper-containing IUD	0.8	0.6	None	Yes
Levonorgestrel IUD	0.2	0.2	Regulation of menstrual cycles and dysmenorrhea	Yes
Female sterilization	0.5	0.5	None	Yes
Male sterilization	0.15	0.10	None	Yes
Etonogestrel implant	0.05	0.05	Same as OCPs	Safety conditional

OCP, oral contraceptive pill; IUD, intrauterine device; STD, sexually transmitted disease.

Data from Trussell J. Contraceptive efficacy. In Hatcher RA, Trussell J, Nelson AL, Cates W, Stewart FH, Kowal D, Policar M, eds. *Contraceptive Technology*, 20th rev ed. New York: Ardent Media; 2011:827–1010; Herndon EJ, Ziemann M. New contraceptive options. *Am Fam Physician*. 2004;69:853–860; Herndon EJ, Ziemann M. *Improving Access to Quality Care in Family Planning: Medical Eligibility Criteria for Contraceptive Use*, 2nd ed. Geneva, Switzerland: Reproductive Health and Research, World Health Organization, 2000. Available at: <http://whqlibdoc.who.int/publications/2004/9241562668.pdf> (accessed July 4, 2006); Speroff L, Fritz MA. *Clinical Gynecologic Endocrinology and Infertility*, 7th ed. Philadelphia: Lippincott Williams & Wilkins, 2005.

the patient make the appropriate decision based on many factors that are unrelated to their medical history or to the side-effect profile of the method, such as the likelihood of compliance and access to follow up.

- Some important considerations in choosing a contraceptive method are its potential side effects, failure rates, and noncontraceptive benefits. See **Table 3-1**.
- Smoking increases the risks of the most dangerous side effects of estrogen-containing contraceptives. This is an important issue in helping a patient choose the safest and the best method. Encouraging smoking cessation is always a good intervention, but one might avoid prescribing an estrogen-containing contraceptive until the patient can truly quit smoking.

- Avoid estrogen-containing contraceptives in women with hypertension or migraine with aura. In both cases, the theoretical or proven risk of stroke outweighs the advantages.

NEWER CONTRACEPTIVE CHOICES

- In addition to the traditional 20 to 35 mcg ethinyl estradiol (EE) OCPs, 30 and 20 mcg EE in combination with the new progestogen *drospirenone* (Yasmin, YAZ) are available. Drospirenone has some antiminerlocorticoid activity and has been shown to decrease the water retention, negative effect, and appetite changes that are commonly associated with menstrual cycle changes.⁴ Serum potassium levels should be monitored when women are at a risk for hyperkalemia. The progestone in these pills often helps in decreasing the severity of acne. Beyaz is a newer formulation of the above with the addition of folate. If a patient becomes pregnant while taking this pill, her folate levels would be adequate to prevent neural tube defects.
- *Extended OCP* regimens with 84 days of levonorgestrel-EE pills and 7 days of nonhormonal pills (Seasonale) are available. Seasonique has the same pills for the first 84 days but uses 10 mcg EE pills for the last 7 days to make up the 91-day cycle. They have similar advantages to other OCPs except that the patient has only four periods a year. Another extended OCP regimen combining levonorgestrel and ethinyl estradiol has been released in which there are no nonhormonal pills at all (Lybrel).
- The *hormonal vaginal ring* (NuvaRing) has similar active ingredients of OCPs, but does not require daily attention (see **Figure 3-1**). It is placed in the vagina for 3 weeks at a time (with 1 week off) and releases EE and etonogestrel. Withdrawal bleeding occurs during the ring-free week. The vaginal ring is associated with a lower incidence of breakthrough bleeding than standard OCPs.
- There is a newer form of Depo-Provera given every 3 months, but given SQ instead of IM. The SQ version provides 30% less hormone, 104 versus 150 mg per injection. It works at least as well as Depo-Provera IM does as a contraceptive, and also works as well as Lupron Depot for endometriosis pain with fewer hot flashes and less bone loss. If long-term use is considered, it may be prudent to select another contraceptive, discuss the risk of possible bone loss, or consider monitoring bone density in women using either version of Depo-Provera for more than 2 years. These medications can increase the incidence of acne and weight gain in some women as a result of the androgenic effects of the progesterone.
- The Mirena *intrauterine device* (IUD) releases levonorgestrel and provides effective contraception for at least 5 years (see **Figure 3-2**). Pregnancy rates are comparable with those occurring with surgical sterilization. Copper-containing IUDs are another long-term option lasting up to 10 years; however, it may be associated with dysmenorrhea and irregular vaginal bleeding some of the time. Twenty percent of women have amenorrhea after 1 year of use with Mirena, and as with the copper-containing IUDs, there is a risk of expulsion. The absolute risk of ectopic pregnancy with IUD use is extremely low because of the high effectiveness of IUDs. However, if a woman becomes pregnant during

FIGURE 3-3 Nexplanon implantable subcutaneous contraceptive system. The insertion device is a sharp trochar and the implant is made of a soft silastic tube. (Courtesy of E.J. Mayeaux Jr, MD.)

FIGURE 3-4 Essure tubal occlusion device for permanent sterilization. It is placed within the fallopian tubes using a vaginal approach and a hysteroscope. (Courtesy of Jay Berman, MD.)

IUD use, the relative likelihood of ectopic pregnancy is greatly increased.⁵

- Nexplanon (etonogestrel implant) is an *etonogestrel-containing single rod implant* for subdermal use (**Figure 3-3**). It is a long-acting (up to 3 years), reversible, contraceptive method. It must be removed or replaced by the end of the third year. The implant is 4 cm in length with a diameter of 2 mm and contains 68 mg of the synthetic progestin etonogestrel (ENG). It does not contain estrogen or latex and is not radiopaque. The contraceptive effect of the ENG implant involves suppression of ovulation, increased viscosity of the cervical mucus, and alterations in the endometrium. In the first year of use, it had the lowest failure rate of any form of contraception, including tubal ligation.⁷ The effectiveness of Nexplanon in women who weigh more than 130% of their ideal body weight has not been studied. Problems with Nexplanon are similar to other progestin-only contraceptives (acne and gaining weight).
- Sterilization by tubal ligation is a common and very effective form of contraception that should be considered permanent.
- Hysteroscopic tubal occlusion (Essure) is a newer technique (**Figures 3-4 to 3-6**). The device is a flexible microcoil designed to promote tissue growth in the fallopian tubes. It does not require any incisions and can be performed without general anesthesia, typically in less than 30 minutes. There is a 3-month waiting period after the device is placed when an alternative birth control must be used. At the 3-month follow-up visit, a hysterosalpingogram is performed to document that the tubes have been blocked.
- The *combination contraceptive patch* (Ortho Evra) releases EE and norelgestromin and has the same mechanism of action as OCPs (**Figure 3-7**). It is applied weekly for 3 weeks, followed by a patch-free week during which menses occur. Recommended application sites include the upper arm, buttocks, and torso (excluding the back and breasts). It has similar efficacy to OCPs but may be less effective in women weighing more than 90 kg (198 lb). In a rare instance of patch detachment, it must be replaced. The progesterone in the patch may decrease the severity of acne.

PATIENT EDUCATION

For some contraceptive methods to be effective, the patient must be willing to use them consistently and correctly. Other methods do not require any action on the part of the patient. Patients will need to understand the benefits and risks of the method they choose and how to be best assured that the method is working for them. If patients are aware of the possible side effects, they can address any such effect with their physician if an adverse effect occurs.

FOLLOW-UP

Monitor for side effects, level of usage, and tolerability. The contraceptive choice should be periodically reexamined as the patient may want to switch to a different method of contraception as needs and circumstances change.

4 PREGNANCY AND BIRTH

Beth Choby, MD
Mindy A. Smith, MD, MS
Leslie A. Shimp, PharmD, MS

PATIENT STORY

As a longtime pregnancy care provider, it was difficult to choose a single story as representative of pregnancy and birth. Most of the stories are meaningful because of the context of the relationship with the woman and the family—a few are tragic and yet filled with grace and the amazing strength displayed by even the very young, some are truly epic tales, and all are learning opportunities. Pregnancy experiences are filled with consternation at the myriad of changes, discomforts, and worries. They are filled with laughter as women's bodies alter in amazing ways; we waddle, unconsciously rest plates on our bellies, and lose sight of our feet (**Figure 4-1**). Our partners and/or supportive others alternate between reassurance and befuddlement. And then a child appears, miraculously from a space that seems far too small to accommodate, and (regardless of the outcome) a new journey begins.

EPIDEMIOLOGY

- Planned pregnancy—Approximately 85% of sexually active women not using a contraceptive method will become pregnant over the course of a year. The probability of conception is 15% to 33% per cycle, depending upon the frequency of sexual intercourse.¹
- Unplanned pregnancy—Half of all pregnancies in the United States are unintended, and approximately half of these unintended pregnancies end in abortion.²
 - Unintended pregnancy (defined as a pregnancy mistimed or not wanted at the time conception occurred) is the result of lack of use of a contraceptive or failure of the contraceptive.
 - Unintended pregnancy occurs among women of all ages, socioeconomic status, and marital status. Although unintended pregnancies are often associated with teens, 41% of pregnancies among women 35 to 39 years of age and 51% of those among women older than 40 years are unintended.³
 - Some unintended pregnancies end in abortions. A total of 827,609 legally induced abortions occurred in the United States in 2007 (16 per 1000 women aged 15 to 44 years).⁴

The highest percentages of reported abortions were for women who were unmarried (82%), white (55%), and aged <25 years (51%). Of all abortions for which gestational age was reported, 62.3% were performed at ≤8 weeks' gestation.⁴
- Maternal mortality has declined dramatically in the United States over the past century. Rates declined from 607.9 maternal deaths per 100,000 livebirths in 1915 to 12.7 per 100,000 livebirths in 2007. Still, maternal mortality over the past 25 years has not improved.⁵ The leading causes of pregnancy-related death are

FIGURE 4-1 Dr. Mindy A. Smith and her husband, Gary, touching bellies during Mindy's pregnancy with Jenny.

embolism (20%), hemorrhage (17%), and pregnancy-induced hypertension (16%).⁶ Major racial disparities continue to exist.

- Maternal mortality (2007) in non-Hispanic black women was 34 per 100,000 live births compared with 10.4 per 100,000 live births in non-Hispanic whites and 9.6 per 100,000 live births in Hispanics. African-American women have 2.7 times the risk of pregnancy-related death compared with whites.
- Care delivery by family physicians (**Figure 4-2**)—Eighteen percent of family physicians perform deliveries as a regular part of their practice; 19.6% perform vacuum extraction; 6.9% do forceps deliveries; 6.3% offer trial of labor after cesarean delivery; and 7.3% perform cesarean deliveries.⁷
- Care outcomes by family physicians—Several studies compare outcomes between family physicians and obstetricians, primarily for comparable patients at low maternal risk (although proportions of high-risk patients are frequently similar across disciplines). One study examining management of vaginal delivery found that obstetricians are more likely to perform episiotomies than family physicians; no difference between groups was noted for instrument use (vacuum or forceps) or neonatal outcomes.⁸ Another study comparing rates of trial of labor attempts and vaginal birth after cesarean (VBAC) rates found a trial of labor attempt rate of 81.1% for family physicians and 50.6% for obstetricians. Success rates were 76.1% for family physicians and 64.3% for obstetricians ($P = 0.002$), although there was a statistically nonsignificant higher uterine rupture/dehiscence rate in the family physician group.⁹

FIGURE 4-2 Family physicians Drs. Scott Fields and Katherine Schlessman have just delivered Jennifer Kam's baby. Dr. Fields has known Jennifer (Dr. John Saultz's daughter—Oregon's Chair of Family Medicine) since she was 6 years old. This is a happy event for all.

ETIOLOGY AND PATHOPHYSIOLOGY

- The most fertile period for women is the several days prior to ovulation and ends 24 hours after ovulation.¹⁰ The ovum is able to be fertilized for only 12 to 24 hours after ovulation.¹⁰
- Sperm usually remain viable for 3 days after intercourse.
- Once the egg is fertilized, it is transported to the uterine cavity in approximately 2 to 3 days. Implantation occurs approximately 6 to 7 days after fertilization following cell division that forms a blastocyst.¹⁰
- Pregnancy is defined by the National Institutes of Health, the American College of Obstetricians and Gynecologists, and the Food and Drug Administration as implantation of the blastocyst in the endometrium.¹¹
- The precise cause of labor is not known but the physiologic changes prior to labor onset include decreased placental progesterone secretion and stimulation of prostaglandin production (E_2 and $F_{2\alpha}$) from the decidua, uterine endometrium, and fetal membranes.
- Labor is defined as progressive dilation of the cervix with uterine contractions. Bloody show (blood-tinged mucus from the vagina), indicating extrusion of the mucus plug, is helpful in predicting impending labor onset.

DIAGNOSIS

A detailed menstrual history should be obtained with the goal of accurately determining the first day of the most recent menstrual cycle. This date is traditionally used to calculate the estimated date of

delivery (EDD) by using Naegele's rule ($EDD = [\text{first day of last menstrual period minus 3 months}] \text{ plus 7 days}$). The rule is most useful in women who have regular 28-day cycles followed by an abrupt cessation of menses.

CLINICAL FEATURES

- Common early symptoms include amenorrhea, nausea, fatigue, and breast tenderness.
- Signs of pregnancy include the following:
 - Alterations in the skin (e.g., a hyperpigmented streak appearing below the umbilicus [linea nigra] and a reddish hyperpigmentation over the bridge of the nose and cheeks [chloasma]) (**Figure 4-3**).
 - Alterations in the vulva, vagina, and cervix (i.e., bluish discoloration [Chadwick sign] caused by vascular engorgement of the pelvic organs and softening of the cervix [Hegar sign]).

LABORATORY

- Pregnancy tests are an accurate marker for pregnancy and use urine (qualitative) or serum (quantitative) to check for β -human chorionic gonadotropin (HCG).
 - Urine tests are generally positive around the time of the first missed period. β -HCG concentrations in the range of 25 to 50 mIU/mL are detectable in qualitative urine samples.
 - Home pregnancy test kits detect β -HCG in the urine. β -HCG is detectable within 1 to 2 weeks after fertilization, but a pregnancy cannot be detected prior to implantation. The highest sensitivity (97%) of home pregnancy tests is at 1 week after the first day of the missed period.
 - Serum pregnancy tests detect β -HCG at levels as low as 10 to 15 mIU/mL and mean levels closely correspond with gestational age during the first trimester. In healthy gestations, β -HCG levels double every 1.4 to 2 days, increasing exponentially until the fetus is 8 to 10 weeks old. Levels then decline somewhat and remain steady throughout the pregnancy. A minimum increase of 66% is expected every 48 hours. An appropriate rise in β -HCG levels on two quantitative (serum) pregnancy tests drawn 48 hours apart is reassuring for normal pregnancy development.

IMAGING

- Transvaginal ultrasound may be used to confirm and date a pregnancy. Sonographic landmarks like the gestational sac and fetal pole correlate highly with β -HCG levels.
 - The gestational sac is generally seen when the pregnancy is 4.5 to 5 weeks along and the β -HCG level is greater than 1000 mIU/mL.
 - The double decidual sign is a thick, hyperechoic (white) ring that surrounds the gestational sac. The yolk sac is the early nourishment for the embryo, seen at 6 weeks when β -HCG levels are greater than 2500 mIU/mL.
 - The fetal pole is seen at 7 weeks gestation with β -HCG levels more than 5000 mIU/mL.
 - Ultrasound measurements of the gestational sac and the crown to rump length (**Figure 4-4**) of the fetus are a very accurate means of establishing the EDD. First trimester transvaginal ultrasound confirms gestational age within ± 7 days.

FIGURE 4-3 Chloasma (melasma) in a young woman after having children. This hyperpigmentation over the cheeks and nose is sometimes called the mask of pregnancy. (Courtesy of Richard P. Usatine, MD.)

FIGURE 4-4 First trimester ultrasound showing crown to rump length. (Courtesy of Richard P. Usatine, MD.)

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of pregnancy includes several gynecologic and nongynecologic conditions. Conditions presenting with an enlarged uterus or abdominal mass include the following:

- Uterine leiomyomas—benign tumors arising from uterine smooth muscle cells. Although most women with symptomatic leiomyomas are in the age range of 30 to 40 years, tumors are occasionally found in adolescents. Myomas occur as single or multiple tumors and range in size from microscopic to large masses. A 20-cm myoma often mimics pregnancy with increased abdominal girth and fullness, but can be distinguished on ultrasound.
- Large adnexal masses and tuboovarian abscesses (TOAs)—The bimanual examination often distinguishes between an adnexal mass and an enlarged uterus. TOA is associated with cervical motion tenderness and abdominal pain. Both conditions can be further evaluated by transvaginal ultrasonography.

Conditions that can present with amenorrhea include the following:

- Hyperthyroidism—Reproductive symptoms can include hypomenorrhea, irregular menses, infertility, and decreased libido. Graves disease is the most common cause among younger patients and common symptoms are nervousness, fatigue, heat intolerance, and tachycardia. Hyperthyroidism is confirmed by a subnormal or undetectable thyroid-stimulating hormone (TSH) and elevated thyroxine (T_4).
- Sheehan syndrome is a form of acquired hypopituitarism; pituitary apoplexy (sudden neurologic impairment resulting from cerebrovascular disorder) can occur in the postpartum period and may result in severe hypoglycemia and hypotension. Acute symptoms include severe headache and bilateral visual changes; long-term symptoms depend on which hormones are deficient (i.e., TSH, follicle-stimulating hormone [FSH], and luteinizing hormone [LH]; prolactin; adrenocorticotropic hormone [ACTH]; and growth hormone [GH]) and the extent of the hormone deficiency. Diagnosis is made with low levels of trophic hormones in conjunction with low levels of target hormones.
- Premature menopause—Menopause, defined as permanent amenorrhea in a previously cycling woman, is considered premature when it occurs before the age of 40 years; approximately 10% of women are menopausal by the age of 46 years. Vasomotor symptoms (e.g., hot flashes) and menstrual irregularity usually precede cessation of menses, the latter by approximately 4 years. An FSH level greater than 40 mIU/mL helps to confirm, but may drop again if ovulatory cycles return.

Conditions that can present with symptoms of pregnancy include the following:

- Ectopic pregnancy is an important diagnosis to exclude in women with a positive pregnancy test, abdominal pain, or vaginal bleeding. Transvaginal ultrasound in combination with serial β -HCG measurements is useful to delineate between intrauterine and ectopic gestation. Heterotopic pregnancies (i.e., concomitant intrauterine and ectopic pregnancies) are seen in 1 in 30,000 gestations.
- Pseudopregnancy is a psychiatric condition in which a woman thinks she is pregnant when she is actually not. She may have symptoms and behaviors consistent with a diagnosis of pregnancy,

including weight gain, abdominal pain, and sensations of fetal movement. Confirmatory lab work is negative, although the woman often cannot be convinced of these results.

MANAGEMENT

- Decision making—Many women and their partners find themselves facing an unplanned pregnancy. Options include continuing the pregnancy and caring for the infant, continuing the pregnancy and placing the infant with an adoptive family, or ending the pregnancy via medical or surgical abortion. Couples need support and information to assist them with this decision.
- Methods to prevent or terminate an unwanted pregnancy include the following:
 - Emergency contraceptives (ECs)—These oral methods can be used after unprotected intercourse or contraceptive failure to prevent pregnancy. These agents are not abortifacients and prevent pregnancy before implantation occurs. They do not disrupt an already established pregnancy and there are no evidence-based medical contraindications to their use. However, ECs, like other hormonal contraceptives, have the potential to inhibit implantation of a fertilized egg.¹¹ The agents are most effective when the first dose is taken within 12 hours of unprotected intercourse; each 12-hour delay in beginning use reduces efficacy by 50%.
 - a. The levonorgestrel product Plan B One-Step reduces the likelihood of pregnancy by 84%. Side effects include heavier menstrual bleeding (31%) and nausea (14%). The standard dosing regimen is one 1.5-mg tablet as soon as possible within 72 hours of unprotected intercourse. Clinical trials demonstrate reasonable efficacy rates up to 120 hours postcoitus. Next Choice is a generic version of the original Plan B and contains two 0.75-mg levonorgestrel doses which may be taken at once or 12 hours apart. Levonorgestrel is available to women age 17 years and older as a nonprescription product. The mechanism of action is delay/inhibition of ovulation; it does not prevent fertilization or interfere with blastocyst implantation. It does not affect an existing pregnancy and will not harm a fetus.¹²
 - b. Ulipristal acetate (ella) is a selective progesterone receptor modulator that is also FDA approved as an emergency contraceptive for use for up to 5 days after unprotected intercourse or contraceptive failure. It is given as a single 30-mg dose; ella is only available by prescription. Use is not approved for patients younger than 18 years of age. Pregnancy should be excluded prior to prescribing ella. It is not known if ella will harm a developing fetus. Side effects include headache (18%), nausea (12%), fatigue (6%), dizziness (5%), and abdominal pain (12%).¹³ The mechanism of action is prevention/delay of the LH surge and follicular rupture—delay of ovulation; it may interfere with implantation of a blastocyst but the 30-mg dose may not prevent implantation (Planned Parenthood, 2010). Ella is more effective than levonorgestrel 72 to 120 hours after unprotected intercourse.¹⁴ Ella may make hormonal contraceptives less effective so a barrier method of birth control (e.g., condom) should be used in addition to hormonal contraceptives for the remainder of that same menstrual cycle.

- c. Use of oral contraceptives containing ethinyl estradiol, plus either levonorgestrel or norgestrel, reduces the likelihood of pregnancy by 75%.¹¹ Approximately 50% of users experience nausea and 20% experience vomiting. Use of oral contraceptives as ECs requires a regimen that includes 2 doses—1 dose taken as soon as possible within 72 hours of unprotected intercourse and the second dose taken 12 hours later. Each dose must include at least 100 mcg of ethinyl estradiol and either 1 mg of norgestrel or 0.5 mg of levonorgestrel.
- Medical abortion (i.e., use of medications to induce an abortion)—Medical abortions account for 12% of the abortions performed in the United States.⁴ Medical abortion is an option for women who wish to terminate a pregnancy up to 63 days' gestation (calculated from the first day of the last menstrual period). The efficacy of the various regimens ranges from 88% to 99%. Regimens including 200 mg of oral mifepristone followed by 800 mcg of misoprostol vaginally from 6 to 8 hours to 72 hours afterwards been shown to be most effective with fewer side effects and lower cost.^{15,16} **SOR A** Side effects of medical abortion using mifepristone and misoprostol include nausea (20% to 52%), thermoregulatory dysfunction (i.e., warmth, fever, chills, hot flashes; 9% to 56%), dizziness (12% to 37%), headache (10% to 37%), vomiting (5% to 30%), and diarrhea (1% to 27%).¹⁵
- Surgical (aspiration) abortion—This method can be performed in the office up to 13 weeks' gestation and has a rate of major complications of less than 1 in 200 cases.⁴ A Cochrane review found no data showing that any one procedure (manual or electrical vacuum aspiration or dilation and curettage) is superior.¹⁷
- Pregnancy care—Despite the widespread use of prenatal care, evidence of its effectiveness is limited. Prenatal care offered by family physicians likely benefits both maternal and infant health by encouraging long-term health maintenance within a continuity relationship and increasing the likelihood that those infants receive timely care. Future research must explore whether enhanced prenatal care benefits certain groups of women, that is, the young, the uninsured, and women in high-risk ethnic groups. Routine visits provide opportunities for screening, management of complications, anticipatory guidance, and educational activities.¹⁸
- First trimester care includes a detailed history to identify medical, health habit, and prior pregnancy problems requiring management (e.g., use of safer medications for pregnancy, smoking cessation, prior gestational diabetes).

An initial pelvic examination is appropriate to detect anatomic defects of the reproductive tract and to screen for gonorrhea and chlamydia.

Screening laboratory tests include blood type (D [Rh] factor), hepatitis B surface antigen, Venereal Disease Research Laboratory (VDRL) (syphilis), urine culture, and HIV for high-risk women. **SOR A**

Blood pressure and weight are monitored.

Folic acid fortified multivitamin supplements once daily are recommended. **SOR A** In a recent metaanalysis, use of multivitamin supplements provided consistent protection against neural tube defects, cardiovascular defects, and limb defects in multiple types of studies, including randomized controlled trials.¹⁹ Folic acid (400 to 800 mcg/day) ideally should be started in the preconception period and continued during pregnancy.

Iron supplementation of at least 30 mg of elemental iron is recommended orally daily (may start in the second trimester). **SOR C** Although demonstrated to increase hemoglobin levels in maternal blood in both the antenatal and postnatal periods, there is limited information related to clinical maternal and infant outcomes.²⁰

Common chronic medical conditions that may require treatment modification or more intense monitoring include asthma (e.g., lowest dose of steroids and stress-dose coverage in labor), hypertension (e.g., safer medication such as α -methyl dopa and consideration of discontinuing diuretics [metabolic abnormalities] and angiotensin-converting enzyme inhibitors [adverse fetal effects]), thyroid disease (e.g., increased thyroid hormone dose is usually needed), and seizure disorders (e.g., possible teratogenesis of phenytoin; 50% have worsening seizures).

- Second trimester care includes continued monitoring, support, and education. Women should be queried about new symptoms and fears, including direct questions about intimate partner violence (present in up to 20% of pregnant women).

Routine measurement of maternal weight, blood pressure, fundal height, and fetal heart tones are conducted. **SOR C** Second trimester screening can include maternal serum tests (e.g., quadruple test combines serum markers of maternal serum α -fetoprotein, estriol, β -HCG, and inhibin A, and detects 86% of infants with Down syndrome [trisomy 21], with a false positive rate of 8.2%), amniocentesis, 1-hour Glucola (gestational diabetes), and an antibody screen for Rh-negative women.

Ultrasound at 18 to 20 weeks' gestation is the standard of care in many regions; however, current evidence fails to correlate routine ultrasound screening in pregnancy with improved fetal outcomes.²¹

Counseling to encourage a healthful diet and moderate exercise.

- Third trimester care includes preparation for birth and newborn care, monitoring, and support.

Evidence-based recommendations include repeat screening for hepatitis B, syphilis, gonorrhea, and chlamydia in high-risk populations (i.e., women younger than age 25 years with two or more sexual contacts, women who are sex workers, and women with prior history of syphilis or gonorrhea) and screening for group B streptococcus (GBS) at 35 to 37 weeks' gestation.

Breastfeeding for 6 months should be encouraged and birth preferences discussed (**Figure 4-5**).

Childbirth classes are often recommended, but evidence supporting their benefit is lacking.

- Labor and birthing:

Labor—Labor is defined as regular uterine contractions with progressive cervical dilation. Effacement, the process of thinning of the cervix, occurs before and during labor. Traditionally, labor has been defined as occurring in three stages:

- a. First stage is divided into latent (1 to 20 hours) characterized by milder and less frequent contractions and active (averaging 5 hours in multiparas and 8 hours in primiparas), where the cervix dilates from 4 cm to complete (10 cm) characterized by stronger, regular contractions lasting 60 seconds or more.

- b. Second stage begins when dilation is complete and ends with the birth of the baby and averaging 20 minutes in multiparas and 50 minutes in primiparas.
- c. Third stage is from the delivery of the baby to delivery of the placenta (up to 30 minutes is considered normal).

Birth requires flexibility and patience. Traditional labor interventions such as withholding food and drink, giving enemas, and perineal shaving have no evidence to support their routine use. Many options are available to increase comfort and ease the process of labor and birth. For example:

- a. Ambulation and frequent changes in position (e.g., side, upright) during labor.
- b. The presence of a supportive labor companion (e.g., partner, doula).
- c. Pain control options include supportive others, physical contact, massage, warm showers, inhaled nitrous oxide, narcotic pain control, and regional analgesia (e.g., blocks and epidurals). Epidural anesthesia is not believed to interfere with the process or outcome of labor, although earlier research suggested an increase in operative delivery rates (e.g. forceps or vacuum).²²

There is no evidence to support routine electronic fetal monitoring,²³ episiotomy,²⁴ or supine birth positions.²⁵

Women who are culture positive for GBS should receive antibiotic prophylaxis when in labor (e.g., intravenous penicillin G [PCN G] in nonallergic women).

FIGURE 4-5 We are privileged to observe this newborn baby breastfeeding for the first time immediately after the delivery performed by Dr. Richard P. Usatine. (Courtesy of Richard P. Usatine, MD.)

PATIENT EDUCATION

- Pregnancy detection with home pregnancy test kits—The first morning urine is the best specimen for testing. The most accurate results are obtained by waiting at least 1 week after the date of the expected period to test. The urine collection container in the kit should be used and the urine tested immediately after collection. If the urine is refrigerated, it should be allowed to come to room temperature (20 to 30 minutes) prior to testing. Common reasons for a test to be read as negative when a woman is actually pregnant include testing too early (i.e., on or before the first day of a missed period), using a waxed cup for urine collection, soap residue in the container used to collect urine, or testing refrigerated urine.
- Pregnancy prevention—Use of contraceptives dramatically reduces the likelihood of unplanned pregnancy (only 8% of women per year using oral contraceptives become pregnant and of women whose partners are using a condom only 15% become pregnant).¹ Many pregnancies occur when a woman discontinues a contraceptive method and does not begin use of another method prior to intercourse; women should be encouraged to have a backup method they can use if the chosen method proves unsatisfactory (see Chapter 3, Family Planning) and should be educated about the availability of the emergency contraception.
- Abortion choices—Since the FDA approval of mifepristone for elective first trimester termination, medical abortion is increasingly common. In 2007, approximately 12% of abortions were performed using combinations of mifepristone and/or misoprostol.⁴
- Pregnancy planning begins with preconception care, ideally occurring 3 to 6 months prior to the conception to discuss health promotion, risk assessment, and medical intervention.

- Environmental exposures that adversely affect the fetus should be minimized (e.g., pesticides, paint thinner/strippers, fertilizers, and heavy metals). Women who work in hospital settings should avoid exposure to ionizing radiation, chemotherapeutic agents, and misoprostol.
- Intake of 400 mcg/day of folic acid prior to and during the early part of pregnancy reduces the risk of neural tube defects. **SOR A**
- Certain heritable genetic diseases can be diagnosed in individuals prior to becoming pregnant (e.g., sickle cell disease, cystic fibrosis).
- Treatment of chronic medical conditions (e.g., diabetes, epilepsy, hypertension) can be optimized to reduce fetal loss and adverse effects, including possible change to medications safer in pregnancy.
- Smoking cessation and eliminating alcohol consumption should be encouraged.
- Immunizations (e.g., rubella, varicella) can be provided.
- Patients should be encouraged to discuss their birthing preferences and their practitioner's practice style with respect to the routine use of technology.

5 END OF LIFE

Mindy A. Smith, MD, MS
Radha Raman Murthy Gokula, MD, CMD

PATIENT STORY

An 89-year-old frail woman presents with Alzheimer dementia, hypothyroidism, depression, congestive heart failure, and macular degeneration. Her functional status was gradually declining. It was difficult for her family to provide 24-hour care and she was admitted to a nursing facility. Her dementia worsened over a period of 2 years in the nursing facility and she became incontinent of urine and feces while developing limitations in speech and ambulation. She could not sit up without assistance and lost her ability to smile and hold her head up independently. The facility was very supportive and a hospice consult was initiated. **Figure 5-1** shows Dr. Gokula along with the hospice nurse visiting the patient for admission to hospice care.

INTRODUCTION

End-of-life care is care that is delivered to patients of all ages who have a very short life expectancy. This care is focused on meeting the patient's emotional and physical needs for symptom relief and general comfort care, and offering patient and family support.

The five basic principles of palliative care are:¹

- Respect the goals, preferences, and choices of the person.
- Look after the medical, emotional, social, and spiritual needs.
- Support the needs of family members.
- Help patients and their families access needed healthcare providers and appropriate care settings.
- Provide excellence in care at the end of life (see **Figure 5-1**).

The quality-of-care domains for a person at the end of life are:²

- Physical and emotional symptom management.
- Support of function, autonomy, personal dignity, and self-respect.
- Advanced care planning.
- Aggressive symptom control near death.
- Patient and family satisfaction.
- Patient's assessment of overall quality of life and well-being.
- Family burden—emotional and financial.
- Survival time.
- Provider continuity and skill.
- Bereavement services.

FIGURE 5-1 Family physician Dr. Murthy Gokula and hospice nurse Chris Emch are comforting and examining a terminally ill patient nearing the end-of-life in Heartland Hospice.

EPIDEMIOLOGY

- Approximately 25,000 children per year in the United States are born with or develop a serious or life-threatening disease such as cancer, cystic fibrosis, cerebral palsy, or muscular dystrophy.³
- According to National Health Center statistics, there were approximately 2.46 million deaths in the United States in 2010; most were attributed to cardiovascular disease and cancer.⁴
 - Among patients ages 1 to 24 years, leading causes of death were external causes (i.e., accidents, homicide, and suicide), followed by cancer and heart disease. As age increases, there is a trend toward chronic conditions being responsible for deaths.
 - The major causes of death in the population ages 25 to 44 years were accidents, cancer, heart disease, suicide, homicide, and other causes.
 - For those ages 45 to 64 years, leading causes of death were cancer, heart disease, accidents, chronic respiratory diseases, and liver disease.

The common causes of death in persons older than age 65 years are heart disease, cancer, chronic lower respiratory disease, stroke, and Alzheimer disease.

- In 2009, heart disease, cancer, chronic lower respiratory diseases, stroke, and accidents accounted for almost 64% of all deaths in the United States.⁵
- Thirty-two percent of all deaths in the United States in 2007 were inpatient hospital deaths.⁶ Average hospital costs for a stay ending in death were \$23,000, approximately 2.7 times higher than for a patient discharged alive.

Hospice services were involved for approximately 20% of dying patients.⁷ More than 70% of hospice patients had cancer and 90% of hospice patients died outside the hospital. The use of hospice and other end-of-life services varies among different racial groups in the United States:⁸

- Whites are more aware of advanced directives when compared to the nonwhite racial or ethnic groups.
- The use of life-sustaining treatments is more common among African Americans when compared to other racial groups.
- Cultural differences are also seen for disclosure of information about a terminal illness. Korean, Mexican, Japanese, and Native American populations are more likely to discourage discussion of terminal illness and patient prognosis and prefer families to be informed.
- The involvement of family in the decision-making process with end-of-life care was seen among all racial groups, but Asian and Hispanic Americans prefer family-centered decision making when compared to other racial and ethnic groups.

ETIOLOGY AND PATHOPHYSIOLOGY

Causes of death are multifactorial. Following are the major modifiable contributors:

- Tobacco use—Of all the adults in the United States, 20.6% smoke cigarettes; the highest rates are among men (23.5%) and American Indians/Alaska Natives (23.2%).⁹ It is estimated that nearly 1 of

every 5 deaths each year in the United States is attributable to smoking.¹⁰ Smoking increases the risk of developing emphysema (10- to 13-fold), heart and cardiovascular disease (2- to 4-fold), and many cancers (1.4- to 3-fold).

- Poor diet—Diets that are high in fat (>40% of calories consumed) are associated with increased risk of breast, colon, endometrial, and prostate cancer. Diet is important in controlling diabetes, heart disease, obesity, and chronic renal disease.
- Physical inactivity—Those who exercise regularly live longer and are healthier; exercise reduces the risk of cardiovascular disease and hypertension and improves function in those with depression, osteoarthritis, and fibromyalgia. Unfortunately less than 20% of adults met the 2008 federal guidelines for aerobic activity and muscle-strengthening.¹¹
- Alcohol consumption—Alcohol is consumed by 80% of the population, and 10% to 15% of men and 5% to 8% of women are alcohol dependent. Excess alcohol consumption (>3 drinks per day) is associated with mood disorders (10% to 40%), cirrhosis (15% to 20%), and neuropathy (5% to 15%); it increases the risk of pancreatitis (3-fold) as well as cancers of the breast (1.4-fold), esophagus (3-fold), and rectum (1.5-fold).¹² In addition, based on data from 2009, an estimated 30.2 million people (12%) ages 12 years or older reported driving under the influence of alcohol at least once in the past year.¹³
- Injury—In 2004, 167,184 people died as a result of injury, accounting for 7% of all deaths.¹⁴ The majority of injury-related deaths are unintentional. Falls are the leading mechanism of injury-related death for elderly people, while for adults 35 to 53 years of age, poisoning is the leading mechanism of injury-related death. Motor vehicles in traffic are the leading mechanism of injury-related death for all other age groups, except for children younger than age 2 years. Many of these deaths are preventable.
- Sexual behaviors—Sexually transmitted infections (STIs) are among the most common infectious diseases and affect approximately 13 million people in the United States each year; most of these people are younger than age 25 years. Sexually transmitted diseases (STDs) are associated with increased risk of HIV/AIDS; in 2007, there were approximately 455,636 persons living with AIDS in the United States.¹⁵ Causes of death from AIDS include infections (especially pulmonary and central nervous system), cancer (especially Kaposi sarcoma and non-Hodgkin lymphoma), cardiomyopathy, and nephropathy.
- Illicit use of drugs—Drug addiction remains a major problem in the United States. According to data from the National Institute on Drug Abuse Monitoring the Future Survey of more than 46,000 eighth to 12th grade students, increases were seen in daily marijuana use (21.4% of high school seniors in the past 30 days) and lifetime ecstasy use in eighth graders (from 2.2% in 2009 to 3.3% in 2010), while decreases were noted in methamphetamine use (from 6.5% in 1999 to 2.2% in 2010) and current cocaine use (from 2.3 million in 2003 to 1.6 million in 2009).¹² Cocaine is associated with death from respiratory depression, cardiac arrhythmias, and convulsions; methamphetamine use is associated with life-threatening hypertension, cardiac arrhythmia, subarachnoid and intracerebral hemorrhage, ischemic stroke, convulsions, and coma.

- Microbial agents—Microbial agents remain a major cause of death and disability with continued discovery of new agents and increasing drug resistance. Although it is difficult to ascertain whether an infectious agent caused death or was incidental to death, the expert panel of investigators in New Mexico, on the basis of autopsy data, found that 85% (106 of 125) of the deaths (late 1994 to mid-1996) were identified as infectious disease related.¹⁶
- Toxic agents—Toxic agents include poisons and environmental toxins. In the United States in 2008, there were 36,500 poisoning deaths; the vast majority were unintentional.¹⁷ Opioid pain medications were involved in more than 40%. Poisoning was the third-leading method of suicide from 2005 to 2007, with 75% a result of alcohol and/or drug overdose. The most commonly used drugs identified in drug-related suicides were prescription drugs in the opioid, benzodiazepine, and antidepressant classes.¹⁸

DIAGNOSIS

It is estimated that approximately 70% of all deaths are preceded by a disease/condition such that it is reasonable to plan for dying in the near future.⁶ These diseases/conditions are as follows:

- Cancer that is widespread, aggressive, or metastatic and for patients who no longer seek curative care. Other clues include a decline in performance status and/or significant unintentional weight loss.
- Dementia with an inability to ambulate, bathe, or dress without assistance; associated urinary or fecal incontinence; inability to meaningfully communicate; or associated with life-threatening infections, multiple stage 3 or 4 skin ulcers, inability to maintain sufficient fluid and calorie intake, or failure to thrive (including a temporal decline in functional status).
- Patients confined to bed or who require assistance with all the basic activities of daily living.
- Patients with a body mass index less than 22 and/or those who refuse or do not respond to enteral or parenteral nutritional support.
- Heart disease that is poorly responsive to optimal medical treatment, New York Heart Association (NYHA) class IV, or congestive heart failure with poor ejection fraction ($\leq 20\%$). Based on data from multiple studies including SUPPORT, Framingham, and IMPROVEMENT, 1-year mortality estimates are as follows: NYHA Class II (mild symptoms), 5% to 10%; Class III (moderate symptoms), 10% to 15%; Class IV (severe symptoms), 30% to 40%. Independent predictors of poor prognosis in patients with heart failure include recent cardiac hospitalization, renal insufficiency (creatinine ≥ 1.4 mg/dL), systolic blood pressure less than 100 mm Hg and/or pulse greater than 100 beats/min, treatment-resistant ventricular dysrhythmias, treatment resistant anemia, hyponatremia, cachexia, reduced functional capacity, and comorbidities (e.g., diabetes).¹⁹
- HIV/AIDS with CD4 count less than 25 or persistent viral load greater than 100,000 copies/mL plus at least one of the following: wasting (loss of 33% of lean body mass); major AIDS-defining refractory infection (e.g., *Cryptosporidium* infection) or malignancy (e.g., central nervous system or systemic lymphoma); progressive multifocal leukoencephalopathy; renal failure; Karnofsky Performance Status (KPS) less than 50%; advanced AIDS dementia complex; or significant functional decline in the activities of daily living.
- Neurologic disease (e.g., Parkinson disease, amyotrophic lateral sclerosis, multiple sclerosis, muscular dystrophy, and myasthenia gravis) that is associated with rapid progression and/or critical nutritional state, life-threatening infections in the preceding 12 months, stage 3 or 4 skin ulcers, critically impaired breathing capacity and declined ventilator support, or life-threatening complications (e.g., recurrent aspiration, sepsis).
- Pulmonary disease, including disabling dyspnea at rest or with minimal exertion, increased emergency department visits and/or hospitalizations, hypoxemia on room air (oxygen saturation $< 88\%$), cor pulmonale, unintentional progressive weight loss, or resting tachycardia greater than 100 beats/min.
- End-stage renal disease with progressive decline in those not seeking dialysis (or not a candidate), with a calculated creatinine clearance less than 10 (< 15 for patients with diabetes) or serum creatinine greater than 8 mg/dL (> 6 mg/dL for patients with diabetes).
- End-stage liver disease with progressive decline in those with refractory ascites, spontaneous bacterial peritonitis, hepatorenal syndrome, hepatic encephalopathy, or recurrent variceal bleeding despite treatment.
- Stroke associated with coma in the acute phase; coma with abnormal brainstem response, absent verbal response, absent withdrawal response to pain, or serum creatinine greater than 1.5 mg/dL at day 3; dysphagia and insufficient intake of fluids and calories; poor functional status; or poststroke dementia.
- Nonspecific terminal illness characterized by a rapid decline, disease progression, or progressive weight loss; dysphasia with aspiration; increase in emergency department visits and/or hospitalizations; worsening pressure ulcers despite optimum care; or a decline in systolic blood pressure below 90 mm Hg.

Unfortunately, physicians are often reluctant to make this determination, resulting in palliative and hospice care not being offered until very late in the course of the illness. In addition, physicians often believe that they must be able to predict a life expectancy of less than 6 months with certainty to institute hospice care.

The National Hospice and Palliative Care Organization has evidence-based guidelines on determining prognosis for a number of noncancer conditions.²⁰ This information can assist clinicians in working with patients who are at the end of life on their advanced care decisions and planning.

Two validated instruments that may help clinicians estimate prognosis are the Palliative Performance Scale (PPS) and the KPS.

- The PPS (http://meds.queensu.ca/palliativecare/assets/pps_scale_tool.pdf) rates information on ambulation, activity and evidence of disease, self-care, intake, and consciousness level. In a retrospective cohort study, the PPS was found to be a strong predictor of survival when applied at admission to patients in palliative care.²¹ In this study, median survival time at PPS of 10% was 1 day, survival with PPS of 20% was 2 days, at PPS of 30% survival was 9 days, while at PPS of 60% median survival was 40 days.
- The KPS (<http://www.hospicepatients.org/karnofsky.html>) is often used to follow the course of illness and is based on performance status ranging from normal (100%) to dead (0%).

CLINICAL FEATURES

Common physical symptoms reported by dying patients:⁶

- Constipation (90%).
- Fatigue and weakness (90%).
- Dyspnea (75%) and other cardiopulmonary symptoms such as cough.
- Pain (36% to 90%).
- Insomnia.
- Other GI symptoms, including dry mouth, anorexia, nausea, vomiting, constipation, diarrhea, and dysphagia.
- Fecal and urinary incontinence.
- Dizziness.
- Swelling and numbness of the extremities.

Common mental and psychological symptoms reported by dying patients:⁶

- Depression (75% symptomatic; <25% with major depression) and feelings of hopelessness, anxiety, and/or irritability.
- Confusion and delirium (up to 85% at the end stage).

A population-based survey of family members, friends, and care givers in six U.S. communities found that:²²

- Seventy-one percent of terminally ill patients had shortness of breath.
- Fifty percent had moderate to severe pain.
- Thirty-six percent were incontinent of urine or feces.
- Eighteen percent were fatigued enough to spend more than 50% of their waking hours in bed.

MANAGEMENT

Management often begins with communicating bad news to patients and families about likely or imminent death. This task can be extremely difficult. In cases where the patient is not deemed legally competent, make sure that the legal decision maker is present. In addition, if the patient is a non-English speaker, consider obtaining a skilled medical interpreter rather than relying on a family member. Providers may find the following P-SPIKES approach useful:²³

- Preparation—Review information to be presented and practice.
- Setting—Arrange time and place, ensure privacy, and include important support persons.
- Perception of patient—Inquire about the patient's and the family's understanding of the illness.
- Information needs—Find out about what the patient and family need to be told and in how much detail.
- Knowledge of the condition—Provide bad news sensitively and slowly, warning them any bad news is imminent and checking to see whether there is understanding.
- Empathy and exploration—Acknowledge the feelings expressed, give the patient and family time to react, and remind them that you are not abandoning them.

- Summary/strategic planning—Discuss next steps or schedule follow-ups to do this if more time is needed.

Roles for the primary care provider include consultation, providing anticipatory guidance, providing support and comfort, and assisting with identifying and managing symptoms (including pain control) (Figure 5-2).

In assisting dying patients and their families/caregivers with making decisions about their care, clinicians should be prepared to discuss the following:

- Realistic treatment options for cure or palliation of the primary disease process.
- Advance directives and withholding of life-sustaining treatment.
- Cultural beliefs and preferences (e.g., truth-telling vs. protecting the patient, religious beliefs).
- Preferences for place of care for those dying, involvement of others, and symptom management.

A number of factors are important in providing optimal care to the dying. In a study of factors considered important to seriously ill patients, recently bereaved family members, and physicians involved in end-of-life care, investigators found the following:²⁴

- There was a general agreement on the items relating to having preferences in writing, symptom control, being kept clean, experiencing physical touch, good communication and knowing what to expect, getting one's affairs in order and achieving a sense of completion, and maintaining dignity and a sense of humor.
- Patients reported wanting to remain mentally aware, not be a burden, and noted the importance of prayer and being at peace with God. They were not as concerned about dying at home.
- Family members reported wanting to use all the treatment options and to help patients avoid pain, shortness of breath, and suffering.

ADVANCE DIRECTIVES

Advance directives and advance care planning continue to be poorly utilized. Clinicians should consider outpatient and inpatient opportunities to introduce these concepts with the goals of empowering the patient and understanding the patient's preferences if they are too sick to speak for themselves. Possible scenarios can be discussed such as recovery from an acute event (specifying acceptable interventions) and persistent vegetative state (preferences for life-sustaining interventions).

- The national POL ST (physician orders for life-sustaining treatment) Paradigm task force is a new program designed to improve the quality of end-of-life care based on effective communication of patient wishes, documentation of medical orders, and a commitment by healthcare professionals to honor these wishes. Information can be found at <http://closure.org> and includes web-based resources for patients and health providers.
- Advance directive documents are of two broad types: instructional directives and proxy designations.
 - Instructional directives, such as living wills, describe decisions about care and healthcare. These can be general or specific. Although 80% of Americans endorse completing living wills, only 20% (and fewer than one-third of healthcare providers)

FIGURE 5-2 Photograph of Marjorie Clarke taken by her grandson. She suffered from Alzheimer disease that left her depressed and frustrated. In this picture, taken in 1996, Marjorie listens to her nurse describe the scene and explain that they are on the front porch of her home. She died in January, 1997. (Courtesy of Marshall Clarke.)

have completed them.⁶ Specific forms do not have to be used and oral directives may be enforceable.²⁵

- Proxy designations—Appointing an individual or individuals to make medical decisions (i.e., durable power of attorney for healthcare).

Legal aspects—The United States Supreme Court has ruled that patients have a right to decide about refusing or terminating medical interventions. Many states have their own statutory forms for living wills.

- The American College of Physicians and the American Society of Internal Medicine End-of-Life Care Consensus Panel note that life-sustaining treatment may be withheld for patients unable to speak for themselves if it is believed to be the patient's wish, the surrogate decision maker states that it is the patient's wish, and/or it is in the patient's best interests to do so.²⁵
- The prescription of high-dose opioids to relieve pain in terminally ill patients that result in death will not lead to criminal prosecution provided it was the physician's intent to relieve suffering.²⁵

HOSPICE CARE AND SERVICES

Hospice care refers to care when curative interventions have been judged to be no longer beneficial. This type of care can be delivered in many settings, including home, hospital, and special residential facilities.

- The types of hospice services include physician and nursing care, home health aides, pastoral care, counseling, respite care, and bereavement programs (**Figure 5-3**).
- Hospice eligibility general guidelines include fulfilling the criteria for end-stage disease as outlined above and documenting both the patient's and family's decision on palliative care rather than curative care and rapid disease progression. In addition, documentation of significant functional decline is important using validated instruments like FAST (Functional Assessment Staging), PPS, BADLs (Basic Activities of Daily Living), and/or NYHA Class IV heart disease. Other criteria include weight loss of 7.5% or 10% in the preceding 3 to 6 months, respectively, or serum albumin less than 2.5 g/dL.

Physicians should be aware of the Medicare Hospice Benefit (MHB) covered under Medicare Part A (physician services are billed under Medicare Part B).²⁶ In the United States, the MHB pays for 80% of all hospice care including medical, nursing, counseling, and bereavement services to terminally ill patients and their families. Medicare beneficiaries who choose hospice care receive noncurative medical and support services for their terminal illness. Home care may be provided along with inpatient care if needed and a variety of other services that are not covered by Medicare. Eligibility criteria are:

- Patient eligible for Medicare Part A or Medicaid.
- Patient is terminally ill, that is, patient's physician and the medical director of hospice certify that the patient is terminally ill and has a life expectancy of 6 months or less if the disease runs its normal course. If the medical director is the patient's physician, only one signature is required.
- Patient chooses hospice care and signs a Medicare hospice benefits form. This process is reversible and patients may at a future time elect to return to Medicare Part A.

FIGURE 5-3 Dr. Alan Blum is a family physician who has been doing sketches of his patients for decades now. When he presents his drawings of his patients, he reads his poetic stories that go with the drawings. Some of his drawings have been published in *JAMA*.

- Hospice care is provided by a Medicare-certified hospice program.
- Under Medicare, do not resuscitate (DNR) status cannot be used as a requirement for admission.

Length of benefits:

- Entitled to receive hospice care as long as he or she meets the eligibility criteria.
- Hospice benefit consists of two 90-day benefit periods, followed by an unlimited number of 60-day benefit periods.
- Benefit periods may be used consecutively or at intervals.
- Patient needs to be certified terminally ill at the beginning of each period.
- No lifetime limit to hospice care for Medicare beneficiaries.
- If patient experiences remission of the disease and is discharged from hospice, the patient can be eligible for hospice care in the future without any regard to the previous use of hospice services.
- The same rules apply for Medicaid patients.

Services covered include physician, nurse, dietician, medical social services, medical supplies and equipment, outpatient drugs for symptom management and pain relief, and home care (e.g., aids, physical, occupational, and speech therapy). Other included services are as follows:

- Short-term general inpatient care for problems that cannot be managed at home—Most commonly intractable pain or delirium.
- Short-term respite care—Up to 5 days to permit family caregivers to take a break (can incur a 5% copayment).
- Counseling in home for patient and family.
- Bereavement, pastoral, and spiritual support for patient and family.
- Payment of consulting physician fees at 100% of Medicare allowance.
- Physician, nurse, social worker, and counselor on-call availability 24 hours a day, 7 days a week.

Services not covered include active treatment of terminal illness (except for symptom management and pain control of the terminal illness), care provided by a physician or facility that has not contracted with the patient's hospice agency, and continuous nursing assistant or nursing home room-and-board charges.

PALLIATIVE CARE

Palliative care is care focused on preventing, relieving, reducing, or soothing symptoms of disease without effecting a cure.²⁷ As such, it is not restricted to patients who are dying, but can be used along with a curative therapy. Many hospitals now have inpatient palliative care services to assist patients, families, and primary care providers in delivering this type of care.

General approach to palliative care focuses on 4 broad domains: managing physical symptoms, managing psychological symptoms, addressing social needs, and understanding spiritual needs.

- Needs assessment—Clinicians should focus on the four domains and try to understand the degree of difficulty and how much the identified problem interferes with the patient's life.
- Setting goals and continuous reassessment—Goals for care include improving symptoms, delaying disability, finding peace, and

providing for the loved ones. Plan times to review these goals as the course of the illness changes or progresses.

- Pain management—There is no reason that patients need to suffer, particularly at the end of life. Barriers to managing pain successfully include limited ability of providers to assess pain severity, fear of sanction/prosecution, and lack of knowledge (including awareness of guidelines).
 - Assessment of pain—Important aspects include periodicity (e.g., continuous), location, intensity, modifying factors, effects of treatments, and impact on the patient.
 - Intervention—This includes nonpharmacologic treatment (e.g., massage, positioning, transcutaneous electrical nerve stimulation [TENS], physical therapy), pain medications, and other palliative procedures (e.g., nerve blocks, radiotherapy, acupuncture).
 - Pain medications may be approached in a stepwise fashion from nonopioids (e.g., acetaminophen [4 g/day], ibuprofen [1600 mg/day]), to mild opioids (e.g., codeine [30 mg every 4 hours] or hydrocodone [5 mg every 4 hours]) to stronger opioids (e.g., morphine 5 to 10 mg every 4 hours).²⁸ Doses should be titrated as needed. Side effects (e.g., constipation, nausea, and drowsiness) should be anticipated and prevented (e.g., laxatives and antiemetic) or treated. Patients may become tolerant to these side effects after approximately 1 week. Specific pain syndromes may require additional consideration. These include:
 - Continuous pain, which requires round-the-clock dosing, rescue medication, and regular assessment and readjustment. If rescue medication has been needed, increase the daily opioid dose by the total dose of rescue medication the next day. For longer duration of action, transdermal fentanyl may be considered (100 mcg/h is equianalgesic to morphine 4 mg/h and has a duration of 48 to 72 hours).
 - Neuropathic pain (arising from disordered, ectopic nerve signals), which is typically shock-like or burning. Medications to consider in addition to opioids are gabapentin (100 to 300 mg daily or up to 3 times daily), 5% lidocaine patch (3 patches daily for a maximum of 12 hours), tramadol (50 to 100 mg 1 to 3 times daily), and tricyclic antidepressants (10 to 25 mg at bedtime titrated to 75 to 150 mg).²⁹
 - Adjunctive analgesic medications are those that potentiate the effects of opioids. These include the above treatments for neuropathic pain, glucocorticoids (e.g., dexamethasone once daily), clonidine, and baclofen.
 - Legal concerns—Physicians may be unwilling or uncomfortable providing high-dose opioids out of fear that they would be hastening the patient's death. However, the assumption that opioids appropriately titrated to control pain hasten death is not supported by medical evidence. In addition, as noted above, the physician's intent to relieve suffering, despite the risk of death, is ethical and unlikely to result in prosecution.

Control of common symptoms:⁶

- Constipation—Secondary to medications, inactivity, poor nutritional/hydration, limited fiber intake, confusion, and intestinal obstruction; comorbidities such as diabetes mellitus, hypothyroidism, and hypercalcemia. The goal of treatment should be one bowel movement every 1 to 2 days. Constipation prophylaxis should be started for all patients taking regular opiate regimens.

Options include increasing fiber, stool softeners (e.g., sodium docusate [Colace] 300 to 600 mg/day orally), stimulant laxatives (e.g., prune juice ½ to 1 glass/day, senna [Senokot] 2 to 4 tablets/day, bisacodyl 5 to 15 mg/day orally or per rectum), and osmotic laxatives (e.g., lactulose 15 to 30 mL every 4 to 8 hours, magnesium hydroxide [milk of magnesia] 15 to 30 mL/day).

- Dyspnea—When possible, treat reversible causes (e.g., infection, hypoxia). Options include opioids (e.g., codeine 30 mg every 4 hours, morphine 5 to 10 mg every 4 hours) and anxiolytics (e.g., lorazepam 0.5 to 2 mg oral/sublingual/IV, diazepam 5 to 10 mg oral/IV). A parenteral infusion or long-acting opiate can also be tried, with bolus dosing for breakthrough pain; nebulized opiates are ineffective for dyspnea.³⁰ For patients with a history of respiratory disease, consider bronchodilators and/or glucocorticoids. For those with excessive secretions, scopolamine may be considered, starting with a low dose every 2 hours, or with worsening dyspnea, as needed. Oxygen is commonly prescribed, although data do not support effectiveness in improving the sensation of breathlessness;³⁰ one crossover trial found ambient air delivered by nasal cannula was as effective as oxygen for dyspnea.³¹ The inexpensive and simple practice of blowing ambient air on the patient's face may help relieve dyspnea.
- Fatigue—Secondary to disease factors (e.g., heart failure, tumor necrosis factor), cachexia, dehydration, anemia, hypothyroidism, and medications. Options include decreasing activity, increasing exercise as tolerated, changing medications, glucocorticoids (e.g., dexamethasone once daily), or stimulants (e.g., dextroamphetamine 5 to 10 mg orally). Modafinil, an analeptic drug, may also be considered (initial dose: 200 mg).
- Depression—Because many of the somatic symptoms used to diagnose depression in healthy individuals are present in patients who are dying, psychological criteria become more important in making treatment decisions. Options include counseling, exercise, and medications (e.g., selective serotonin reuptake inhibitors); low doses should be used initially (e.g., fluoxetine 10 mg/day) and increased as needed. Psychostimulants (e.g., dextroamphetamine or methylphenidate 2.5 to 5 mg twice daily) may be considered if rapid onset of action is needed; these may be used in conjunction with traditional antidepressants.
- Delirium—Secondary to metabolic abnormalities (liver failure, electrolyte disturbance, vitamin B12 deficiency), infection, brain tumors, medications, and multiple other causes. Options include treating reversible causes and medications including neuroleptics (e.g., haloperidol 0.5 to 5 mg orally/subcutaneous/IM/IV every 1 to 4 hours, risperidone 1 to 3 mg every 12 hours), anxiolytics (e.g., lorazepam 0.5 to 2 mg oral/IM/IV), and anesthetics (propofol 0.3 to 2 mg/h continuous infusion).

ADDRESSING SOCIAL NEEDS

Considerations include economic burden and caregivers.

- The U.S. health insurance system is neither universal nor comprehensive and many patients and their families find themselves under tremendous financial strain.
- Twenty percent of terminally ill patients spend more than 10% of the family income on healthcare costs beyond insurance premiums.⁶

- Ten percent to 30% of families need to secure additional monies by means such as selling assets or taking out a second mortgage to cover healthcare costs.⁶
- Twenty percent of caregivers stop work to provide care for a terminally ill family member.⁶
- Families/caregivers often need outside help, such as providing personal care for the patient (such as bathing), psychological or spiritual counseling, respite care, or making arrangements for the body after death.
- Primary care providers can facilitate encounters with family and friends by offering their presence and suggestions about easing the visits (e.g., reading to the patient, sharing music, or creating a videotape, audiotape, or scrapbook).
- Hospice and social workers can offer great assistance to patients and families in addressing these needs.

Understanding spiritual needs:

- Approximately 70% of dying patients become more religious or spiritual at the end of life.
- As noted by Steinhauser et al., patients noted the importance of prayer and being at peace with God.²⁴
- Physicians should ask about and support patient and family expressions of spirituality and consider encouraging pastoral care, as desired.

PATIENT AND FAMILY EDUCATION

It is very important to involve patients and their families in discussion at an early stage as most want to know their diagnosis and prognosis.

- The role of the primary care physician should be discussed, particularly if other providers are involved in the care of the patient. Possible roles include consultation about care needs, anticipatory guidance on prognosis and expected symptoms, provision of support and comfort, and assistance with managing symptoms.
- Families usually suffer emotionally, spiritually, and financially as they care for the patient.²¹ Family members often experience a sense of hopelessness, anger, guilt, and powerlessness when they cannot relieve the suffering of their terminally ill family member.
- Families who need to provide care for a terminally ill patient should be made aware of community resources and the provisions in the Family Medical Leave Act.³²
- It is not unusual to see hidden family conflicts resurface in the face of a terminal illness, and any emotional tension that exists between the caregivers and patient can impede care. Physicians should be sensitive to the conflicts and cultural influences and closely observe how patients and their families are communicating so that they can better support them, allowing them to express their emotions and concerns and referring them to appropriate counselors or support groups when needed.^{33,34}
- Children should not be excluded from this process and the physician, with permission, can help in determining what children already know about the illness and in providing accurate information about the diagnosis, prognosis, and treatment expectations for the dying family member. Also advise caregivers to try to maintain

the children's daily schedule and routines of the family as much as possible, monitor for problems at school, encourage questions, and plan activities (e.g., reading a story) when visiting ill family members. It may be helpful to inform teachers and counselors at school about the family situation and request that the teachers let the parent know if the child is having any difficulty or talks about worries.

- Consider counseling for the child if the child requests help or displays symptoms of depression or anxiety that interfere with school, home, or peers; risk-taking behavior; or significant discord with others.

The following are processes that many dying persons go through:

- Social withdrawal—Initial withdrawal is from the surroundings and then worldly interests decline and finally withdrawal from family, ultimately leading to loss of communication.
- Decreasing nutritional requirements—There is a decreased need for fluids and solids; fluids are usually preferred and should follow what the patient wants rather than force-feeding.
- Disorientation—There is increased confusion with time, place, and person. Usually patients talk about seeing people who have already died or state that their death is nearing. Redirecting the patient is necessary only if asked for or if the patient is distressed.
- Decreased senses—Hearing and vision decrease. Using soft lights helps with decreasing visual hallucinations. Speak softly and gently as patients hear even at the end of life. Hearing is the last of the five senses to be lost.
- Restlessness—Also called “terminal restlessness” is caused by the change in the body's metabolism. Reassurance is important, and appropriate symptom management with medications may be helpful.
- Sleep—There is increased time spent in sleep that may be as a result of changes in the body's metabolism or natural to the underlying disease process. Spending time at the bedside can help capture the time when the patient is most alert.
- Incontinence of urine and bowel movements is often not a problem until death is very near. Absorbent pads can be placed under the patient for greater comfort and cleanliness or a urinary catheter may be used for comfort care. The amount of urine will decrease and becomes darker at the end of life.

Physical changes to be expected include the following:

- Skin color changes including flushing, bluish hue to the skin, and cold sensation of the skin. Skin may have a jaundiced look when the patient is approaching death. The arms and legs of the body may become cool to the touch. The hands and feet become purplish. The knees, ankles, and elbows are blotchy. These symptoms are a result of decreased circulation.
- Blood pressure decreases; the pulse may increase or decrease.
- Body temperature can fluctuate; fever is common.
- Increased perspiration along with clamminess.
- Respirations may increase, decrease, or become irregular; there may be periods of cessation of breathing (apnea).
- Congestion can present as a rattling sound in the lungs and/or upper throat. This occurs because the patient is too weak to clear the throat or cough. The congestion can be affected by positioning,

may be very loud, and sometimes just comes and goes. Elevating the head of the bed and swabbing the mouth with oral swabs may be helpful.

- The patient may enter a coma before death and not respond to verbal or tactile stimuli.

FOLLOW-UP

Withdrawal of life-sustaining treatment:

- Evidence-based criteria for guiding physicians through this process is lacking; however, general consensus exists based on ethical and clinical principles in the care of these patients.^{35,36}
 - Withdrawal of life-sustaining treatment can be considered when curative care is not possible and supportive or other treatment is no longer desired and does not provide comfort to the patient.
 - Withholding life-sustaining treatment is morally, ethically, and legally equivalent to withdrawing life support. Any kind of treatment that is given to the patient can be withdrawn or withheld. In conducting these discussions with patients and their families, the physician needs to consider a patient's information-sharing preferences (e.g., a preference for limited information), minimum acceptable quality of life and functional status, whether the patient is able to understand the consequences of life-sustaining treatment, whether procedures offered conflict with the patient's values, and the patient's need for advice and guidance.³⁷
 - Treat withdrawal of life-sustaining treatment equivalent to a medical procedure and all formalities (e.g., informed consent) should be fulfilled prior to the procedure.
 - If withdrawal of one life-sustaining treatment is indicated, then consider withdrawing all existing treatments for the patient.
- A general consensus should be reached with the healthcare team and family members that is in the best interest of the patient. Following are the steps that should be taken for withdrawal of life support:³⁶
 - Informed consent.
 - Appropriate setting and monitoring.
 - Sedation and analgesia.
 - Having a plan for withdrawal (information about the protocol can be found in fast facts at www.eperc.mcw.edu).
 - Pastoral, nursing, and emotional support.
 - Documentation.
 - Interventions to improve care during withdrawal of life-sustaining treatment that can be considered are consultation with an ethics committee, palliative care team, family conferences, and a standardized order form for withdrawing life-sustaining therapies.³⁸

Grief and bereavement follow-up:

- Manifestations of grief consist of both psychological symptoms (e.g., sadness, anxiety, emotional lability, apathy, impaired concentration) and physical symptoms (anorexia, change in weight, trouble initiating or maintaining sleep, fatigue, headache). In the first month following a death, it is important to reassure surviving family members and friends that these manifestations of grief are normal and to offer support, suggestions for symptom management, and coping resources.

- Subsequent follow-up visits should be used to assess the progress of mourning and to identify depression; if the latter is identified, consider pharmacotherapy and counseling.
- Usually, the primary physician is notified of the death and may be required to make the pronouncement (based on lack of vital signs and lack of response to noxious stimulus) and complete the death certificate (noting cause of death and contributing medical conditions).
- Following the death of the patient, personal expressions of condolence from the primary care provider(s) and staff should be encouraged and range from cards to attending visitation and the funeral; based on personal experience, the latter can assist with grieving and closure for the physician.

6 SOCIAL JUSTICE

Mindy A. Smith, MD, MS
Richard P. Usatine, MD

Of all the forms of inequality, injustice in health care is the most shocking and inhumane.

—Martin Luther King, Jr.

The first question which the priest and the Levite asked was “If I stop to help this man, what will happen to me?” But ... the Good Samaritan reversed the question: “If I do not stop to help this man, what will happen to him?”

—Martin Luther King, Jr.

PATIENT STORIES

At only 5.5 pounds (10 pounds less than the fifth percentile for weight on the World Health Organization’s growth chart), an 8-month-old boy suffered from severe malnutrition. In the summer of 2003, amidst the height of Liberia’s civil war, his aunt brought him to the Médecins sans Frontières/Doctors without Borders hospital for treatment. Because of the war, his family had been forced to flee from their home, leaving behind their usual methods of getting food. Dr. Andrew Schechtman was there to help the day the child was brought to the clinic in Liberia (**Figure 6-1**). Despite the best available treatment for the malnutrition and concurrent pneumonia, the boy died on his third hospital day.

OUR STORIES AS CARING CLINICIANS

Those of us who become family physicians or other healthcare providers do so for many reasons. One reason is because of a desire to help someone else. Along the way, we sometimes lose ourselves in the day-to-day struggles, the disappointments, the obligations, the fatigue, and the profound helplessness that descends upon us after a particularly bad day. But we are still here and, if we listen with our hearts, we are still capable of great and small things.

We are privileged in so many ways and we must recognize our power over ourselves and over the communities that we serve. It is easy to become overwhelmed by the problems that we face as clinicians and as fellow human beings. Our healthcare system is in shambles, our natural world is being poisoned, our nations are continually at war, and yet, as this chapter highlights, there is so much that we can do—we can listen, we can observe, we can witness, we can bring aid, we can touch, we can love, and we can lead.

The text that follows highlights just a few examples of the ways in which our colleagues are challenging themselves to find creative solutions to the many problems faced by those who are underserved, displaced, or suffering.

FIGURE 6-1 Dr. Andrew Schechtman was there to help the day a severely malnourished child was brought to the clinic in war-torn Liberia. Despite the best available treatment that could be provided in the Doctors Without Borders hospital, the child died of complications of malnutrition and pneumonia—a casualty of war and poverty. (Courtesy of Andrew Schechtman, MD.)

DOCTORS WITHOUT BORDERS (ANDREW SCHECHTMAN, MD)

EPIDEMIOLOGY

The United Nations (UN) High Commissioner for Refugees reported that in 2011 there were 10.9 million refugees (those displaced across an international border) and 27.5 million internally displaced persons (IDPs, those displaced within their own country).¹ At the end of 2010, the UN refugee agency was caring for an estimated 14.7 million of these IDPs. During times of a complex humanitarian emergency (defined as a humanitarian crisis in a country, region, or society where there is a breakdown of authority resulting from internal or external conflict and which requires an international response that goes beyond the mandate or capacity of any single agency and/or the ongoing UN country program), the following usually occur:²

- Civilian casualties.
- Populations besieged or displaced.
- Serious political or conflict-related impediments to delivery of assistance.
- Inability of people to pursue normal social, political, or economic activities.
- High security risks for relief workers.

ETIOLOGY

People can be displaced from their homes by manmade (war, persecution) or natural disasters (tsunami, earthquake, or hurricane). War is responsible for most of the displacement. Some of the source countries accounting for the most refugees are Afghanistan, Sudan, Somalia, the Palestinian territories, and Iraq.

- Communicable diseases usually cause the most illness and deaths in humanitarian emergencies in less-developed countries. Children younger than 5 years of age are the most vulnerable.² Other priority areas include provision of adequate, safe water, food, shelter, and protection from violence.
- In addition to the usual causes of illness and death in emergency-affected populations in less-developed countries (measles, malaria, pneumonia, and diarrhea), crowded settlements may be prone to outbreaks of cholera, meningitis, and other diseases, which can be rapidly spread. Such outbreaks may be explosive and cause many deaths in a relatively short period of time.

PROBLEM IDENTIFIED

In times of stability, writes Dr. Andrew Schechtman, many of the poorest people in the world succeed in their struggle to meet basic needs for shelter, food, and water. When displaced from their homes by manmade or natural disaster, communities and extended families are disrupted, access to food and water are lost, and

marginal circumstances become desperate. Displaced people are often dependent on the support of the international aid community to meet their basic needs.

BEING PART OF THE SOLUTION

When infrastructure collapses as a result of manmade or natural disasters, access to healthcare can be limited or nonexistent. Serving as a volunteer physician with Medecins sans Frontieres (Doctors Without Borders) allowed Dr. Schechtman to provide medical care to people in desperate circumstances who had nowhere else to turn for assistance. Bearing witness to tragedies such as the case described in **Figure 6-1** gave him another means to help, that is, the authority to speak out on behalf of victims like this child, focus public attention on the situation, and encourage political pressure to bring the fighting to an end.

ACCESS AND ADVOCACY: PROSTHETIC PARITY (JEFF CAIN, MD)

EPIDEMIOLOGY

Health insurance reform is on the minds of many, as the US citizens debate the pros and cons of President Obama's healthcare bill. In the midst of this debate, many people find themselves without health insurance. The 2010 U.S. Census Bureau reported that the percentage of people without health insurance (16.3%) although not statistically different from the rate in 2009, resulted in an increase in the number of uninsured people from 49.0 million to 49.9 million; this percentage of uninsured is 4% higher (representing 5.1 million more people) than at the first writing of this book in 2005.³

- Lack of insurance disproportionately affects Hispanics (30.7% are uninsured), followed by blacks (20.8%), Asians (18.1%), and non-Hispanic whites (11.7%).⁴ (**Figures 6-2** and **6-3**)
- According to the American College of Physicians 2000 report, uninsured Americans may be up to three times as likely as privately insured individuals to experience adverse health outcomes and up to four times as likely as insured patients to require both avoidable hospitalizations and emergency hospital care.⁵
- Uninsured adults have a 25% greater mortality risk than adults with coverage; approximately 18,000 excess deaths among people younger than age 65 years are attributed to lack of coverage every year.⁶
- In 2007, 62% of personal bankruptcies were caused by medical bills, a rise of almost 50% since 2001.⁷ Importantly, of those bankruptcies, three quarters were actually insured at the time of their illness.

One area where insurance coverage may be limited is for prosthetics, where coverage may consist of a single lifetime prosthesis or be placed under restrictive arbitrary caps that cover less than a third of the cost. Unfortunately, limb loss is fairly common and risk is greatest among vulnerable populations:

FIGURE 6-2 This mother and child are being cared for in the University of California at Los Angeles (UCLA)/Salvation Army free clinic run by medical students for homeless families in a transitional housing village. The boy had a bacterial infection on his leg and required antibiotics. The computer system in a pharmacy rejected his name and number, but, fortunately, the family doctor advocated for this child and the medicine was obtained. (Courtesy of Richard P. Usatine, MD.)

FIGURE 6-3 This 18-year-old mother has had type I diabetes since age 13 years. As a single mom she qualified for one of the living units within the Salvation Army transitional housing village. The week before this photo was taken, she presented to the student-run free clinic with diabetic ketoacidosis secondary to running out of her insulin. She knew that she needed her insulin but the pharmacy would not fill it because her insurance appeared to have lapsed in the computer system. After many calls to many pharmacies with no luck, her needed insulin was obtained from another free clinic in town. She survived without hospitalization and was feeling much better at the time of this photograph. (Courtesy of Richard P. Usatine, MD.)

- In 2005, 1.6 million people (approximately 1 in 190) in the United States were living with limb loss.⁸
- In 1997, 131,218 hospital discharges had a lower extremity amputation (LEA) discharge diagnosis code.⁹ Regardless of comorbidity, these rates were higher for men than women and higher for non-Hispanic blacks than for Hispanics or non-Hispanic whites.⁹ According to the *Disparities in Health and Health Care among Medicare Beneficiaries*, the rate of amputation is four times greater in blacks than in whites.¹⁰

ETIOLOGY

- Most cases of limb loss are as a consequence of vascular disease (54%), trauma (45%), and cancer (<2%).⁷
- Of the 1997 hospital discharges noted above, 67% were related to diabetes.⁹ The age-adjusted LEA rate for persons with diabetes (5.5 per 1000 persons) was 28 times that of persons without diabetes (0.2 per 1000 persons).
- Nearly half of the individuals who have an amputation as a consequence of vascular disease will die within 5 years.¹¹ This is higher than the 5-year mortality rates for breast cancer, colon cancer, and prostate cancer.
- Of persons with diabetes who have a LEA, up to 55% will require amputation of the second leg within 2 to 3 years.¹²

PROBLEM IDENTIFIED

As a practicing family physician in Denver, Colorado, Jeff Cain had already been a leader for health advocacy in cocreating a tobacco-free education program for children called Tar-Wars. This program has grown from a local Denver activity into an international campaign reaching more than 8.5 million children in all 50 states and in 14 countries.

Dr. Cain became acutely aware of insurance disparity for patients with disabilities when a 1996 airplane accident resulted in a LEA and he was surprised to find his hospital residency's insurance policy provided only \$1000 for a year's prosthetic benefits, far short of the needed cost. Although he was fortunate to be able to afford the much larger copay for his prosthetics himself, most Americans could not. Indeed, he found that most insurance companies did not provide enough coverage for most amputees to afford the necessary prosthetics to fully live their lives.

BEING PART OF THE SOLUTION

To change the situation, Dr. Cain (**Figure 6-4**) founded and led the Colorado Coalition of Working Amputees, a grassroots organization whose work led to Colorado becoming the first state to pass "prosthetic parity" insurance legislation in 2001. This legislation required insurance companies to pay for artificial arms and legs.

Following this success, Dr. Cain joined the board of directors of the Amputee Coalition of America where he provided vision and leadership establishing the Coalition's Action Plan for People with Limb Loss. The Amputee Coalition created a tool kit modeled on materials

FIGURE 6-4 Dr. Jeff Cain in his advocacy role at the Capitol in Washington, DC in 2010. Dr. Cain's highly rated speaking presentations have focused on youth tobacco prevention, healthcare reform, and adaptive devices. (Courtesy of Jeffrey Cain, MD.)

FIGURE 6-5 Dr. Cain at Jackson Hole on a Ski-bike in 2004. His participation in sports continues to encourage and inspire many adaptive athletes. (Courtesy of Jeffrey Cain, MD.)

developed by the Colorado Coalition of Working Amputees, which has been used by grassroots organizations across the country to advocate for changes in insurance laws on the state level. This work has led to 20 states passing insurance mandate legislation with 16 introducing legislation and 8 states organizing for introduction of legislation in 2012. Dr. Cain participated in Hill Visit days in 2010 and 2011, resulting in the introduction of the 2012 federal Fair Insurance Access for Amputee bill, and was instrumental in President Obama's signing of a proclamation for April 2012 as Limb Loss Awareness Month.

Dr. Cain encourages others to advocate for justice using personal stories that help us connect with each other and with the larger community. He states, "A story has superpowers for persuading people of the importance of your cause. If you can combine your story with the facts and economic reality, people will line up with your position."

As current president of the American Academy of Family Physicians, Dr. Cain continues his leadership and advocacy work. In addition, as a sports enthusiast and gold medal winner in adaptive slalom snowboarding (**Figure 6-5**), Dr. Cain works to develop and share ways to adapt sports equipment for use by people with limb loss (**Figures 6-6** and **6-7**), improving quality of life and health through exercise.

REFUGEES AND ASYLUM SEEKERS (LUCY CANDIB, MD)

EPIDEMIOLOGY

A refugee is a person who is outside his or her country of nationality or habitual residence; has a well-founded fear of persecution because of his or her race, religion, nationality, membership in a particular social group, or political opinion; and is unable or unwilling to avail himself or herself of the protection of that country, or to return there, for fear of persecution. Worldwide, in 2010, there were approximately 15.6 million refugees and approximately 27.5 million persons displaced within their own countries.¹³

An asylum seeker is an individual who has sought international protection and whose claim for refugee status has not been determined yet. As part of its obligation to protect refugees within its territory, the country of asylum is normally responsible for determining whether an asylum seeker is a refugee or not. As of January 2011, there were 264,574 officially settled refugees residing in the United States and 6285 asylum seekers.¹⁴

An "asylee" is someone who has been granted asylum. They are the same as a "refugee" at that point. The only difference is their process of becoming a refugee. Asylees receive protection through seeking asylum from within the United States, whereas refugees seek safety from their location abroad. Those who get to the United States are chosen for resettlement to the United States after being granted protection. Each year the United States agrees with the United Nations High Commissioner for Refugees to take a specified number of refugees from designated countries. Within those countries, many other refugees are declared refugees but are not resettled. The United Nations or other refugee agency may choose to keep them in a camp, integrate them locally in the country they fled to, or send them to another country that accepts refugees.

FIGURE 6-6 Dr. Cain "hanging zero" on two prosthetic legs. (Courtesy of Jeffrey Cain, MD.)

FIGURE 6-7 Dr. Cain in a 2010 bike race despite two prosthetic legs. (Courtesy of Jeffrey Cain, MD.)

Within the United States, legally resettled refugees are able to work and can obtain medical care through routine systems of care. Asylum seekers, who must place their application for asylum within 1 year of entry into the United States, are unable to work or receive any government benefits, and have no coverage for any preventive or curative healthcare.

Many asylum seekers have been victims of violence in their country of origin and have experienced a very high rate of torture (defined as an act committed by a person acting under the color of law specifically intended to inflict severe physical or mental pain or suffering [other than pain or suffering incidental to lawful sanctions] upon another person within his custody or physical control) (**Figures 6-8 and 6-9**).¹⁵

- For example, from more than 2000 applications for asylum from Turkish nationals (primarily Kurds) to the United Kingdom in 2003, investigators interviewed and examined 97 individuals requiring medical evaluation for evidence of torture.¹⁶ A wide variety of injuries and psychological disorders were documented, including posttraumatic stress disorder (PTSD) and major depression.
- In the United States, at a mental health center in California serving survivors of torture and refugee trauma, a chart review of 134 consecutive asylum seekers (two-thirds women) showed that 82% were diagnosed with PTSD and 96% with a depressive disorder. Some reports had a high risk of a history of torture, rape (odds ratio [OR] = 4.23), political persecution (OR = 9.28), and symptoms of PTSD (OR = 4.93).¹⁷
- However, unless specifically being questioned about their past experiences of trauma and torture, refugees are unlikely to disclose their history. In a 2003 study from three community clinics in Los Angeles, only 3% of torture victims told their physicians about their experience.¹⁸

ETIOLOGY

- In a study of 89 asylum seekers from 30 countries, commonly reported reasons for abuse were political activity (59%), ethnicity (42%), and religion (32%).¹⁹ Types of abuse in this population included punching/kicking (79%), genital electrical shock (8%), and rape (7%). Persistent psychological symptoms were common; 40% had PTSD.
- Increasingly, gay and lesbian asylum seekers are surfacing within the United States because of persecution of homosexuals in their countries of origin, including torture, death threats, and murder of publically identified gay and lesbian figures.
- For an asylum seeker, proving “persecution” to an immigration officer or a judge within the United States may be very difficult if he or she escaped with few or no documents from his or her country. The asylum seeker may be unable to communicate with family out of fear of disclosure of their location. The asylum seeker’s family members may also still be at risk of detention and torture by officials trying to extract information about the location of the asylum seeker. The legal application process can include a medical and psychological evaluation to support the history of persecution the person experienced, including ongoing harassment of the asylum seeker’s family and friends.

PROBLEM IDENTIFIED

Dr. Lucy Candib is a family physician working at a community health center in Worcester, MA, a city of 168,000 people that has been a home to immigrants for hundreds of years. She has always been committed to cross-cultural medicine and has cared for patients and families from all over the world since her early training. She has a long-standing commitment to work with women survivors of physical and sexual violence, but had never been involved in a formal way in working with immigrants seeking political asylum. She writes, "I started about 10 years ago with an evaluation of a woman from Kenya fleeing severe physical violence from her husband. Her story was emblematic of everything I had ever learned about battered women, including marital rape, the abduction of the children, and threats and harm against the woman's own parents."

BEING PART OF THE SOLUTION

Dr. Candib attended a 1-day training for medical professionals offered by Physicians for Human Rights and recently attended their advanced training program. She works regularly with the local refugee and immigrant settlement organizations to conduct physical examinations and provide medical documentation for their clients who were seeking political asylum in the United States. She also involves her residents in working with these patients. She describes the process as follows:

- The asylum lawyer contacts me to schedule an evaluation and sends me the materials relevant to his/her client's case and to the country of origin about once every 1 to 2 months.
- I meet with the man or woman, often from a country in West Africa. I usually start with situating the person in their family and their region, and then move slowly into eliciting a history of the events that unfolded in their experiences of persecution, imprisonment, torture, and flight. I include a full medical history and review of their current symptoms. This detailed process may take 1 to 3 sessions, depending on the person's ability to tell his/her story and tolerate the feelings that always emerge when recounting it.
- Afterwards, I do a physical examination, carefully documenting scars by measurement and photographs and describing any physical injuries resulting in pain or limitation of movement. I include an assessment of their mental and emotional condition. I do these assessments at the health center on my days off, as these long sessions do not fit in the short medical appointments in my regular schedule.
- Drawing on my notes, I then provide a narrative history and examination in a formal document for the asylum hearing and attach any relevant photographs. Some pictures leave no room for doubt: the symmetrical scars on both sides of the scalp of a man who had been clubbed by police wielding truncheons, or the ridged scalp and skull of a man struck by a hoe across the top of his head by his captors (**Figures 6-8** and **6-9**). Often I do some research on the Internet to understand how my clients' experiences fit into the overall political history of their country. This documentation work takes anywhere from 5 to 10 hours for each individual. The lawyers tell me that my assessments weigh heavily in their clients' favor at the hearings. Most recently, I have been involving second- and third-year family

FIGURE 6-8 This African man suffered a depressed skull fracture when he was detained for his political activity. His captors struck him with a hoe. He heard his own skull crack open and fell to the ground bleeding. His captors left him for dead, but he was able to struggle to a roadside where he was brought to safety by a passerby.

FIGURE 6-9 A skull radiograph showing the depressed skull fracture in the patient in **Figure 6-8**.

medicine residents in this work. They, too, are stunned and then gratified by the intensity and immediacy of the work.

Dr. Candib concludes saying, “This work has changed me as a human being. After 35 years of clinical practice with low-income families, moments come when I feel that my work has been slow and incremental. But this work—engaged in advocacy that directly affects a person’s future—reaffirms that I *can* make a clear and immediate difference, 1 person at a time. This is also humbling work. These individuals teach me not only about what unspeakable pain humans inflict on each other, but also what amazing strengths each person carries inside. These patients teach me about myself and how much I don’t understand or know about any given person in front of me in the examination room, and, at the same time, teach me about the world. Without leaving Worcester, I become a doctor without a border, acting on behalf of others while growing myself.”

CARING FOR THOSE WITH DISABILITIES (LAURIE WOODARD, MD)

EPIDEMIOLOGY

Approximately 54 million Americans currently live with at least 1 disability and the vast majority (52 million) live in their communities (Figure 6-10).²⁰

- According to data from 1999, the prevalence rate of disability was 24% among women and 20% among men.²¹ Approximately 32 million adults had difficulty with 1 or more functional activities, and approximately 16.7 million adults had a limitation in the ability to work around the house. Two million adults used a wheelchair and 7 million used a cane, crutches, or a walker.
- Of children ages 3 to 17 years, 4.9 million were told that they have some type of learning disability and 12.8% (9.4 million) have special healthcare needs.²⁰
- Racial and ethnic minorities have higher rates of disabilities than whites or Asian Americans; 7.3 million individuals (ages 15 to 65 years) with disabilities are of racial or ethnic minorities.
- In 2005, the surgeon general issued a Call to Action to improve the health and wellness of persons with disabilities underscoring the need in this population.²⁰

ETIOLOGY

Challenges to a person’s health can happen at any age and at any time. Disabilities are not illnesses, rather they are limitations related to a medical condition that have an influence on essential life functions such as walking, seeing, or working.²⁰ Furthermore, disabilities do not affect all people in the same way.

- Of all the adults with disabilities, 41.2 million (93.4%) reported that their disability was associated with a health condition including arthritis and rheumatism (17.5%), back or spine problems (16.5%), heart trouble/hardening of the arteries (7.8%), lung or

FIGURE 6-10 Dr. Laurie Woodard and her daughter Anika share a good laugh following breakfast while on vacation in New Mexico. Although Anika is dependent for all her activities of daily living and is nonverbal because of spastic quadriparetic cerebral palsy, she loves to travel and has a wonderful sense of humor.

respiratory problems (4.7%), deafness or hearing problems (4.2%), mental or emotional problems (3.7%), blindness or visual problems (3.4%), and intellectual disability (2%).²¹

- Rates of disability are increasing in part because of the aging population, better survival of catastrophic illnesses and trauma, and advances in preventing infant and child mortality.

PROBLEM IDENTIFIED

As a mother of a child with profound disabilities, Dr. Laurie Woodard found that her medical training did little to prepare her for caring for her child or finding help (**Figure 6-10**). She became acutely aware that people with disabilities had great difficulty finding physicians and those who provided care often seemed afraid of them. She said, “I couldn’t imagine someone not wanting to care for her because she had a disability.” Physicians tend to focus on the medical condition and not the whole person and their families; when confronted with the patient’s healthcare needs and functional issues, the feeling of acting more like a social worker than a physician caused them to fall back into medical model framework. In addition, societal support for those with disabilities, particularly disabilities acquired as an adult, are fragmented and the primary care physician needs to become the link.

BEING PART OF THE SOLUTION

Dr. Woodard began to care for increasing numbers of patients with disabilities, training herself through reading, experience, and asking patients what worked. As she worked with individual students she planned for a time when she could break into the medical student curriculum to provide this training. Eight years ago, when the curriculum for third-year students underwent major reform, she saw her opportunity. Within the primary care 12-week experience, a curriculum on special populations was planned and Laurie made sure that it included teaching about persons with disabilities. Her curriculum, implemented in 2005 with goals ranging from sensitivity training to understanding both the capabilities and needs of individuals with disabilities, contains the following components:

- Clinic-like experience with 8 to 10 patients with physical disabilities (e.g., cerebral palsy, communication issues, wheelchair users) where pairs of students complete brief interview and physical examination under video monitoring. The session ends with a debriefing circle wrap up with students and patients.
- Panel discussion with patients with varying abilities who usually represent an advocacy agency or organization. Special emphasis is placed on community services and opportunities including the arts and sports.
- Home visits where student pairs (2 medical students or a medical student and physical therapy student) receive a preparation sheet and checklist and learn how disability affects individuals and their family. Following the visit, students prepare reflection plus research reports that are posted on blackboard; part of the assignment is to read and comment on all the papers.
- Service learning project where students give presentations on health topics (e.g., first aid, influenza) selected by staff at an adult

daycare facility for individuals with intellectual disabilities or the high school group noted above, or assist in the recreational activities for individuals with disabilities (e.g., free physicals for riders in therapeutic horseback riding program).

- An objective structured clinical examination (OSCE) case involving a manual wheelchair user with shoulder pain; the standardized patients are individuals who are wheelchair users.
- Sensitivity training session, run by Parks and Recreation where students are randomly assigned a disability (e.g., using a wheelchair or other assistive device or blindfold) and complete tasks followed by watching the movie *Murderball* (an informative and proactive documentary about the Paralympics sport, quadriplegic rugby, and its players). A speech pathologist also provides a hands-on assistive/augment communication device tutorial.

“The students learn to see the patient first,” she says, “that caring for these individuals requires recognizing the patient’s expertise about their disability and problem solving together. For most students, even the most jaded, this is simply an eye opening experience as the patients are usually quite physically impaired but lead full and active lives” (Figure 6-11).

Dr. Woodard has expanded this program and is co-teaching with faculty from the School of Physical Therapy (PT) so that medical and PT students interview and examine patients together. In addition, she will begin providing training within the courses Doctoring 1 and Doctoring 2 to first- and second-year medical students (the home visit and panel discussion will be moved to the first year) allowing more complex and challenging issues to be addressed during the clerkship. Finally, she is also involved with Alliance for Disability in Health Education, a group mainly out of the Northeast whose mission is to get the American Association of Medical Colleges (AAMC) to require the topic of disability in the curriculum.

Since the initial publication of this chapter, Dr. Woodard’s daughter graduated from high school in June 2011. The family is working on helping her structure her day and move beyond the interminable wait list for services to which she is entitled. She is happy and healthy and the family members consider themselves lucky to have good, affordable caregivers and companions to assist her.

CARING FOR THE HOMELESS (RICHARD P. USATINE, MD)

EPIDEMIOLOGY

At least 643,000 persons were homeless on any given night in 2009 and 1 in every 200 Americans (approximately 1.56 million people) spent at least 1 night in a shelter during that year.²² Of those who were homeless in one study, 3% reported having HIV/AIDS and 26% reported other acute health problems, including tuberculosis and other sexually transmitted infections.²³

Causes of death were investigated in one study of 40 homeless people for more than a 1-year period (1985 to 1986) conducted by the Fulton County Medical Examiner in Georgia. It was thought at that time that between 4000 and 7000 individuals were homeless, so the crude death rate for that year was estimated at 5.7 to 10 per 1000.²⁴

FIGURE 6-11 Dr. Woodard, daughter Anika, and dog Nikki are part of a team of University of South Florida (USF) medical students, faculty, and family who participated in a “wheel-a-thon” to raise money for Tampa’s first fully accessible playground. Teaching medicals students the therapeutic value of sports and recreation for people with disabilities is an important aspect of the USF curriculum.

- Black males accounted for 19 (48%) of the 40 deaths, white males for 18 (45%), and black females for 3 (8%). The median age for 36 individuals whose age was known was 44 years (range = 21 to 70 years).
- Twenty-two individuals (55%) died or were found dead outdoors. Of the 18 persons who died indoors, 7 were found in vacant buildings and 5 died at shelters.
- Cause of death, based on the medical history, investigation scene information, circumstances of death, and autopsy and toxicologic studies (when performed) was classified as natural (16), accidental (19), or homicide (4) or suicide (1). Natural deaths included alcohol related (9 including 3 with seizures likely from alcohol withdrawal), heart disease (4), and lung disease (3). Accidental deaths were primarily a result of acute alcohol toxicity (7), fire (6), hypothermia (2), and pedestrian–motor vehicle incidents (2). No deaths were attributed to drugs other than alcohol.

ETIOLOGY

Homeless persons are often extremely poor and socially isolated, the latter is considered a significant contributor to being homeless. Many medical conditions are caused by or exacerbated by the adverse living conditions and lack of healthcare experienced by the homeless. These include:

- Psychiatric illnesses (as many as 40% of homeless persons).
- Physical health problems, including injuries from trauma, respiratory disease (e.g., tuberculosis), scabies and pediculosis infestations, and chronic illnesses such as diabetes.

PROBLEM IDENTIFIED

Dr. Usatine has worked with homeless individuals and families for 28 years. Their stories and lives have touched his heart and soul in profound ways. He writes, “the homeless in America are at the bottom of our society in dire poverty and lacking a stable living environment. Losing a job and a home and suffering with mental illness and addictions make the homeless one of the most vulnerable populations in our wealthy country.”

BEING PART OF THE SOLUTION

In 1984, Dr. Usatine began to provide healthcare to homeless people at the Venice Family Clinic, a free clinic in Venice, CA. Along with Mary Smith, NP, a seasoned nurse practitioner who had years of experience working with the homeless, he delivered healthcare to the homeless of Los Angeles both in the free clinic and in the surrounding shelters. Dr. Usatine was also the medical director of a nurse-practitioner-run full-time free clinic in the largest homeless shelter on skid row of Los Angeles. Working with Aaron Strehlow, NP, PhD, they made care accessible to the approximately 1000 homeless persons staying in that shelter on a daily basis.

He first established 2 student-run clinics for homeless families and individuals with the medical students of UCLA. He states that the

“passion and motivation of the students to serve this vulnerable population has been a tremendous inspiration to him throughout his career.” After moving to San Antonio, Texas, Dr. Usatine worked with medical students to establish 2 more student-run clinics: one for homeless families and another for women in a residential drug and alcohol treatment home (Figures 6-12 and 6-13).

The students and faculty of University of Texas Health Sciences Center at San Antonio (UTHSCSA) have created a whole program called FOCUS (Free Outreach Clinics for the Underserved in San Antonio). Three new clinics have been created, including 1 interdisciplinary clinic for refugees, 1 for free dermatology care, and 1 working with Haven for Hope. Haven for Hope is a transformational village for homeless individuals and families in San Antonio. It is a large collaborative effort by many people and agencies and shows students what can be done when good people work together for the benefit of their community.

- Dr. Usatine has made it easier for medical students to volunteer their time in the student-run clinics by creating approved courses that give students credit for their work with the homeless. Currently he is running a “Humanism Fellowship” in which fourth-year medical students work throughout their fourth year to take leadership roles in managing and directing the student-run clinics under faculty supervision. The elective supports and nourishes the inherent altruism of the students. A second elective “Homelessness and Addiction” is available to first and second year students who want to work in the clinics and learn more about the populations they serve. Both courses are prime examples of Community Service Learning (CSL) and exist under the umbrella of the Center for Medical Humanities and Ethics.
- As part of these experiences, students are asked to reflect on their work with the homeless. This comment from one student perhaps best expresses what many students have written about providing care to this vulnerable population, “Seeing how difficult it is to get back on your feet has greatly impacted how I treat those who are struggling. It has taught me that I am blessed with such a gift of providing healthcare that I should give back without any expectations of reimbursements or praise. I realize what a difference I can make in the lives of those who are homeless by providing them not only with healthcare but encouragement. It has taught me to be blind to those with and without insurance and to treat everyone equally regardless of their social background. It has made me more appreciative of the comforts that I take for granted and how easily we can be living in a bubble.”

Dr. Usatine strongly believes that these students will be better physicians for the experiences in these student-run clinics. He states, “It is wonderful to be part of the solution to help people who have slipped through the cracks of the healthcare system get the healthcare they need. It is especially rewarding to see medical students put their hearts and souls into caring for this population.” Students learn compassion and are inspired by the efforts being made by their patients to get their lives back together. They are always amazed by the tragic stories of abuse, violence, poverty, and deprivation that many of their patients have lived through.

Dr. Usatine also takes medical students on medical mission trips to Ethiopia, Haiti, Dominican Republic, Guatemala, and Panama, and codirects a Global Health Elective in his medical school. Working

FIGURE 6-12 In an effort to help women recovering from substance abuse, the students and faculty of University of Texas Health Sciences Center San Antonio partnered with Alpha Home to open a free clinic on site. Alpha home is a residential treatment unit with a 40-year track record of helping women become clean and sober. Prior to the opening of this clinic within the home in which the women reside, most of these uninsured women would go to the crowded university emergency department for healthcare. Many went without healthcare for fear that a 36-hour wait would drive them back to drugs and alcohol. The photograph shows (from left to right) Melanie Lane, the head counselor; Amy Cantor, the student founder; Julie Wisdom-Wild, the CEO; and Richard P. Usatine, the faculty founder and advisor.

FIGURE 6-13 Amy Cantor as a fourth-year medical student in the Humanism Fellowship caring for a family at the second student-run clinic established in San Antonio. The mom and her 4 children have been reunited at the San Antonio Metropolitan Ministries Transitional Living and Learning Center. We saw this family almost weekly in our clinic and helped them make the transition from homelessness to independence. (Courtesy of Richard P. Usatine, MD.)

with impoverished populations abroad is a natural extension of the work being done at home. Dr. Usatine states, “We partner with other humanitarian organizations abroad so that our work has a longer lasting impact on the people we try to help. We try to bring equipment and provide training to people in these countries so that we are not just popping in and leaving the people with not much but a few medications. These experiences transform the lives and world views of our medical students and we hope they will continue to be inspired to give to people in global and local communities throughout their careers.” (Figures 6-14 and 6-15).

DISPARITY IN CAREERS IN MEDICINE (CRYSTAL CASH, MD)

EPIDEMIOLOGY

According to data from the AAMC, about one-quarter of U.S. medical school graduates practicing medicine in 2008 were of minority race; blacks comprised only 6.3%, 5.5% were Hispanic or Latino, 12.8% were Asian, and 0.5% were Native American/Alaskan Native.²⁵ Of black physicians, the vast majority (70.4%) were in office-based practice and 9.2% were in hospital-based practice (with an additional 20.3% who were residents and fellows); the percentages are similar for physicians of other races.

- With respect to specialty, higher proportions of Native American/Alaskan Native (23.6%), Hispanic or Latino (14.0%), and black (13.6%) physicians were in family medicine or general practice compared to 12.7% of whites and 7.1% of Asians.²⁵
- In the report on *Minorities in Medical Education* (2005), only 1% of black physicians were in medical teaching (compared with 0.9% of Hispanics, 0.4% of Asians, and 0.4% of Native Americans). This lack of diversity is problematic for many reasons including workforce distribution; minority physicians are more likely to provide care for minority and indigent patients and to practice in underserved areas (51% of black, 41% of Native American, and 34% of Hispanic graduates in 2004 intended to practice in underserved areas compared with 18.4% of whites).²⁶
- In 2011, 59.7% of students enrolled in U.S. medical schools were white and 7% were black.
- Over the past 3 decades, the percentage of white male physicians graduating from U.S. allopathic medical schools has decreased from a peak of 10,323 in 1982 to 5,346 in 2008.²⁵ The number of white women has steadily increased from 1714 in 1978 to 4728 in 2008. Over the same period, similar trends were seen among black physician graduates; black men are poorly represented with 429 graduates in 2008 (down from 474 in 1978) whereas increases were seen for black women (763 in 2008 up from 250 in 1978). Following initial increases for both Hispanic (or Latino) men and women, in 2008 the graduation numbers for men had fallen so that slightly more women than men graduated (460 vs. 459).

FIGURE 6-14 Dr. Richard P. Usatine with a young HIV-positive girl in rural Ethiopia during a mission trip with eight medical students. The year before we helped her get diagnosed and treated for tuberculosis, HIV, and tinea capitis. Her mom died of HIV and now she lives with her grandmother and goes to school at Common River (an NGO that helps many families in Aleta Wondo). Now 1 year later she is healthier and happier. (Courtesy of Tsegaye Bekele, Common River.)

FIGURE 6-15 Matt and Annie (two UTHSCSA medical students) spotted a young boy lying still in the tall grass just inside the metal gates of the government health clinic in rural Ethiopia. He was alone, not moving, and his skin was burning hot. Matt (with EMT experience) leapt into action and scooped the boy up from the grass running with him into our makeshift clinic. Matt yelled for Dr. Usatine as he placed the boy on the only examination table. The boy was barely conscious but was able to cooperate with an oral thermometer which read a surprising 41.5°C (106.7°F). After treatment with IV fluids and antibiotics for a presumed meningitis, Abraham woke up. Unfortunately, at 10 years old he had already been living on the streets by himself for 4 years. The following morning the medical students gathered food from their breakfast to take it to Abraham. Abraham was awake and his fever was gone. The students were delighted to see Abraham sitting on the side of his bed looking well. He gave them a big smile in greeting. The students gathered around Abraham as he devoured the food, barely taking a moment to breathe between bites. Two years later, Abraham lives and attends school at Common River. He is a great student and a very kind and helpful person. (Courtesy of Richard P. Usatine, MD.)

- Of 114,087 medical school faculty in 2005, 71.9% were white, 12.6% were Asian, 4.0% were Hispanic, and 3.1% were blacks.²⁶ Minority faculty were primarily at the rank of assistant professor, with 9% to 19% at full professor, compared to whites, where nearly 30% were at the rank of full professor.

ETIOLOGY

- Lack of representation of minorities in medicine is likely multifactorial and includes lack of educational opportunity and encouragement, prejudice, and lack of mentoring.
- Problems in the pipeline from kindergarten to grade 12 play an essential role in hindering the numbers of ethnic and racial minorities from applying to medical school.²⁶
- Blacks and Hispanics have lower rates of graduating from high school than whites.
- Only 39.9% of blacks and 34% of Hispanic high-school graduates enrolled in college from 2000 to 2002, compared to 45.5% of whites.

PROBLEM IDENTIFIED

In an attempt to improve test scores in a failing Chicago public school, the school was divided into three institutes, one of which is the Daniel Hale Williams Prep School for Medicine. Dr. Cash was one of the several physicians from Provident Hospital (also founded by Dr. Daniel Hale Williams) who were invited to an open house called “Doctor’s Day.” The idea for a mentoring program sprang from the days’ activities to provide access for kids to practicing physicians.

BEING PART OF THE SOLUTION

- The Future Doctors of America Club (**Figure 6-16**) proposes that through leadership training and skills development, the students themselves can become resources and will mentor other students.
- The program is based on principles similar to the school’s mission—to have the students become physicians through improved resources and hands-on activities.
- Mentors were assigned one to three mentees and mentor–student experiences included shadowing, tutoring, advising, volunteer activities, and social interaction.
- “In our first year,” writes Dr. Cash, “we inducted 27 students into the club, and by 2006 we added another 54 students. We developed guidelines for mentors, students, and for parent participation. The students developed their organizational structure, vision, and mission statements as well as a schedule of desired activities. Activities, including a medical boot camp, were associated with service learning hours and skills development.”

Since the first edition of this book, the program is no longer affiliated with Dr. Cash’s institution. However, of the 72 students who participated in this program as junior high school students, all graduated high school and 58 are now attending 4-year colleges. Most students received scholarships to offset some of the tuition costs. Dr. Cash remains in touch with some of her former students and is hopeful that many will ultimately seek careers in medicine.

FIGURE 6-16 Dr. Crystal Cash working with inner-city students in The Future Doctors of America Club. This peer education session was held at a Chicago Public School (Daniel Hale Williams Preparatory School for Medicine).

7 GLOBAL HEALTH

Ruth E. Berggren, MD
Richard P. Usatine, MD

COMMUNITY STORY

Common River is a U.S.-based nongovernmental organization (NGO) implementing a community development program in Aleta Wondo, Ethiopia. This NGO is founded on the principle of positive deviance, in which local best practices are identified and replicated to maximize agricultural production (organically grown coffee is produced in this region), as well as to improve the nutritional status, health, and education of orphaned and vulnerable children. Since 2009, a group from the University of Texas School of Medicine has travelled annually to Aleta Wondo to provide school health screening and free healthcare, including treatment of endemic helminth infections, trachoma, and skin diseases, while collaborating with and supporting the local government-sponsored health clinic (**Figures 7-1A and B**). In **Figure 7-1C**, the schoolchildren of Common River are looking at the new group of American medical students that have just arrived in Africa. In the coming week, these children will receive oral albendazole to treat intestinal parasites and have complete physical exams to detect and treat other common conditions, such as head lice, tinea capitis, trachoma, and foot infections. Note that many of the children are barefoot. In **Figure 7-1D**, a group of women has just completed their woman's literacy class for the day. Improving women's literacy can improve the health of the entire community.

WHAT IS GLOBAL HEALTH?

For years, the term *international health* has described health work in resource-limited settings with an emphasis on tropical diseases, communicable diseases, and illness caused by poor nutrition and inadequate access to water, sanitation, and maternal care.¹ More recently, *global health* is commonly used to emphasize mutual sharing of experience and knowledge, in a bilateral exchange between industrialized nations and resource-limited countries, and the emphasis is expanding to include noncommunicable diseases and chronic illness.² One definition of global health, proposed by the Consortium of Universities for Global Health Executive Board, is “an area for study, research, and practice that places a priority on improving health and achieving equity in health for all people worldwide.”¹ This chapter focuses on a few conditions commonly encountered in developing nations, emphasizing communicable diseases and malnutrition.

Ethical dilemmas abound when professionals from resource-rich settings leave their familiar environment and apply their practices in a severely resource limited setting. Consider, for example, breastfeeding guidelines in the setting of maternal-to-child HIV prevention. National protocols differ depending on resource availability. In some settings, telling an HIV-positive mother not to breastfeed (because breast-milk can transmit HIV) may sentence her infant to near-certain death from diarrhea. If a program overturns local teaching about exclusive breastfeeding, it must ensure a safe and sustainable alternative

FIGURE 7-1 A. Many people still live in extreme poverty with no running water and electricity. This is a typical hut in Ethiopia. This one is inhabited by a grandmother, her grandchild and a cow. The photograph was taken after a home visit to provide IM ceftriaxone to the child after her release from the local hospital where she was treated for a neck abscess and cellulitis. The medical team was staying at Common River and originated from the University of Texas. (Courtesy of Richard P. Usatine, MD.) B. Usatine, MD.)

form of infant feeding. Imposing the standards of industrialized nations in a community that cannot afford to continue to provide these standards can undo years of program development. Care must be taken not to undermine the trust a community has placed in local health providers, as this can ultimately increase morbidity rather than relieve suffering. Working with local health providers is essential so that a short trip can result in extended benefits to the community (Figure 7-2).

This chapter briefly introduces some of the relevant subject areas with which global health providers should familiarize themselves when preparing for international work. Statistics that aid in understanding the state of a nation's health relative to other countries are the mortality rate of children younger than age 5 years old and adult life expectancy. Least-developed countries report that as many as 112 of 1000 children die before age 5 years, compared to 8 per 1000 in developed countries,³ and adult life expectancy ranges from 48 or 49 years at birth (Chad, Swaziland) to 88 or 89 years (Japan, Monaco).³ Another important parameter by which to compare the health status of countries is that of maternal mortality, defined as the number of maternal deaths per 100,000 livebirths. These figures, together with basic epidemiology of disease provide important insights into public health priorities for populations.

What statistics do not provide, however, is the level of importance ascribed to a particular health issue by a community. It is necessary to acknowledge and address the needs expressed by communities themselves, in order of their own priorities, so as to achieve sustained improvements in health outcomes. All health improvements ultimately rely on long-term behavioral changes, whether dietary, pill taking, physical activity, or hygiene related. Group behavioral change requires buy-in from the population with approbation and influence of local leadership.

A useful method of creating a positive impact is to make use of ongoing peer-to-peer adult education techniques through the introduction of community health clubs. This can be effective for empowering resource-limited communities to develop their priorities, and to advocate for their community health and development needs.⁴ It is best to learn about and collaborate with the local and governmental community health activities before launching any intervention, be it clinical, infrastructural, or preventive.

WATER AND SANITATION

Many diseases in resource-poor settings are traceable to deficits in clean water supply and storage, lack of soap for bathing, and lack of functioning infrastructure to manage human waste (garbage collection, latrines) (Figure 7-3). Some of the most important ones include typhoid fever, cholera, and intestinal parasites.

Lack of governmental and public health infrastructure in the developing world leads to large populations living without clean running water. World Health Organization (WHO) and UNICEF estimate that 780 million persons are without access to improved water sources and 2.5 billion (37% of the world's population) people are without access to improved sanitation sources.⁶

Water and sanitation deficiencies are responsible for most of the global burden of diarrheal disease. The most common diarrheal disease of returning travelers is caused by enterotoxigenic *Escherichia coli*. All over the world, young and malnourished children die of preventable diarrhea caused by rotavirus, *E. coli*, *Salmonella*, *Shigella*, and *Campylobacter*.

FIGURE 7-2 The physician in the front of this picture is pleased to receive medications that are unavailable to her hospital in rural Panama. Before shipping or bringing medications abroad, it is essential to learn what practicing physicians need. Bringing redundant or nearly expired meds or short-term supplies of expensive brand medications causes more harm than good. Donated medications should be locally relevant generics that are not expired. The WHO list of essential medications may be helpful in planning (<http://www.who.int/medicines/publications/essentialmedicines/en/index.html>). (Courtesy of Richard P. Usatine, MD.)

FIGURE 7-3 A. A covered pit latrine serving the needs of an Ethiopian family. The latrine is located on the edge of the garden near their home, and presents a fall hazard for young children. (Courtesy of Richard P. Usatine, MD.) (continued)

Diseases that are particularly deadly as a result of lack of access to clean water include typhoid fever and cholera. Intestinal parasites, while usually not deadly, do lead to chronic problems with malnutrition and anemia, which themselves contribute to cyclical poverty and disease because they lead to impaired learning, reduced productivity, and vulnerability to other infectious diseases.

TYPHOID FEVER

Typhoid fever, also known as enteric fever, is an acute systemic illness caused by the invasive bacterial pathogen, *Salmonella typhi*. *Salmonella* is ingested in contaminated water or food, invades the mucosal surface of the small intestine, and causes bacteremia, with seeding of the liver, spleen and lymph nodes.

EPIDEMIOLOGY

Typhoid fever is mainly found in countries with poor sanitary conditions. Because most such countries do not routinely confirm the diagnosis with blood cultures, the disease is highly underreported. Outbreaks of typhoid are often seen in the rainy season, and in areas where human fecal material washes into sources of drinking water. Shallow water tables and improperly placed latrines are environmental risk factors for typhoid. Globally there are 16 to 33 million cases annually, with up to a half a million deaths every year.⁷

CLINICAL PRESENTATION

Patients develop an acute systemic illness with prolonged fever, malaise, and abdominal pain after ingesting contaminated food or water. This truly nonspecific syndrome may include headache, mild cough, and constipation, with nausea and vomiting. Diarrhea may be present but it is not the rule. After a 10- to 20-day incubation period, there is a stepwise progression of fever over a period of 3 weeks, and the patient may display a transient rash described as rose spots (2- to 4-mm pink macules on the torso, which fade on pressure). Temperature pulse dissociation with relative bradycardia despite high fever may be noted in fewer than 25% of patients. In the second week, the patient becomes more toxic and may develop hepatosplenomegaly. Untreated, typhoid can progress to include delirium, neurologic complications and intestinal perforation caused by a proliferation of *Salmonella* in the Peyer patches (lymphoid tissue) of the intestinal mucosa. Although the mortality rate for untreated typhoid is 20%, early antibiotic therapy can decrease mortality. Approximately 1% to 4% of those who recover from acute typhoid fever become carriers of the disease who continue to shed *Salmonella* in their stool despite not being ill.⁷

DIAGNOSIS

Culture of blood, stool, rectal swab, or bone marrow.⁸

DIFFERENTIAL DIAGNOSIS⁹

- Malaria (often clinically indistinguishable from typhoid; empiric therapy for both malaria and typhoid may be warranted if diagnostic testing is unavailable).
- Enteroinvasive *E. coli*
- *Campylobacter*

FIGURE 7-3 (Continued) B. An Ethiopian pit latrine, which offers no mitigation for flies and is situated in proximity to the water table below. Heavy rains will lead to contamination of the water supply with fecal pathogens. (Courtesy of Richard P. Usatine, MD.) C. An elevated, ventilated improved pit latrine can protect the water table and reduce flies. Air circulates down the squat hole, into the pit and up through the pipe. To ensure unhindered flow of air, the top of the vent pipe must be 0.5 meters above the top of the shelter. The latrine interior is kept dark so the main light source in the pit comes from the vent pipe. Flies are attracted to the light, but the pipe has a fly-proof screen at the top, so they cannot escape and eventually die.⁵ Many countries consider the ventilated improved pit latrine to be the minimum standard for improved sanitation. (Courtesy of Jason Rosenfeld, MPH.)

- Paratyphoid fever (*Salmonella para typhi*, other less virulent *Salmonellae*)
- Dengue fever (mosquito borne arbovirus infection spread by *Aedes aegypti*)
- Rickettsial diseases (typhus, spotted fever, Q fever)
- Brucellosis
- Leptospirosis
- Heat stroke

MANAGEMENT

Prompt diagnosis and initiation of antibiotic therapy is essential and life-saving. Oral rehydration therapy should be initiated first, followed by IV fluids if vomiting cannot be controlled and for patients with altered mental status or hypovolemic shock. Antibiotic resistance patterns differ with geographic location.

For Africa and resource-limited settings in the Americas, the first choice is chloramphenicol 1 g PO daily for 10 to 14 days, or ciprofloxacin. Historically, trimethoprim-sulfamethoxazole 960 mg PO twice daily for 10 to 14 days has been used,⁸ but there has been increasing drug resistance to sulfa in these areas. In Asia, where multi-drug resistant *S. typhi* strains are well described, ciprofloxacin (500 to 750 mg twice daily), ceftriaxone (60 mg/kg IV daily) or azithromycin (500 mg daily) may be used for 7 to 14 days.⁸⁻¹⁰ Azithromycin should only be used in mild disease. Some guidelines advocate the use of dexamethasone, 3 mg/kg IV followed by 1 mg/kg every 6 hours for 2 days in the setting of shock or altered mental status.⁸ See vaccine information at the end of this chapter.

CHOLERA

Cholera is an acute, diarrheal disease caused by *Vibrio cholerae*. It is usually transmitted by contaminated water or food, and is associated with pandemics in countries that lack public health infrastructure and resources for sanitation. Although the infection is often mild or asymptomatic, in 5% to 10% of patients it can be severe and life-threatening.¹⁴

EPIDEMIOLOGY

V. cholerae reservoirs occur in brackish and salt water, as well as estuaries. Although the organism occurs in association with copepods and zooplankton, its largest reservoir is in humans. Cholera pandemics have been reported in south Asia, Africa, and Latin America. Characteristically, cholera outbreaks occur in countries that have suffered destruction of public health infrastructure (collapse of water supplies, sanitation, and garbage collection systems). The 2010 outbreak in postearthquake Haiti has been traced to UN Peace-keeping soldiers, whose waste contaminated a major Haitian river used for bathing, irrigation, and drinking water. In just 10 months, 300,000 cases were reported, of whom 4500 died, and the outbreak has continued to wax and wane with the rainy seasons for years.¹¹ A large infective dose is necessary for infection, and although only approximately 10% of those infected fall ill, the infection can be fatal for young children, elderly, and malnourished individuals.

PATHOPHYSIOLOGY

V. cholerae is a motile, gram-negative rod. After ingestion via contaminated water or food, it must survive the acid environment of the

stomach before colonizing the mucosal surface of the small intestine. The organism is noninvasive, and not associated with bloody diarrhea. Rather, it makes a potent toxin causing massive secretion of electrolyte-rich fluid into the gut lumen. Human to human contact spread virtually never occurs. Transmission through contaminated food or water is the rule.¹²

Clinical presentation ranges from mild watery diarrhea to acute, fulminant watery diarrhea which looks like rice water. After an incubation period of 18 to 40 hours, patients may lose up to 30 L of fluid daily, with resulting metabolic acidosis and electrolyte disturbances. Severe dehydration can lead to death in a matter of hours. Vomiting, when present, starts after the onset of diarrhea. Profoundly dehydrated patients present with decreased skin turgor, sunken eyes, and lethargy. Children, but not adults, may have mild fever. Cramping caused by loss of calcium and potassium is common.¹²

DIFFERENTIAL DIAGNOSIS AND LABORATORY TESTS

Early presentation may resemble enterotoxigenic *E. coli*; however, the syndrome is quickly distinguishable because of the extreme volume of “rice water” secretory diarrhea that is the result of cholera toxin. *V. cholerae* may be confirmed by stool culture, polymerase chain reaction (PCR) for toxin genes, or dark-field microscopy with specific antisera, which will immobilize the *V. cholerae*.¹³ The Centers for Disease Control and Prevention (CDC) recommends confirmation of cholera by stool specimen culture or rectal swab. For transport, Cary Blair media is used, and for identification, thiosulfate-citrate-bile-salts (TCBS) agar is recommended.¹⁴

MANAGEMENT

Water, sanitation, and hygiene education is essential, as is education about recognizing the symptoms and immediately seeking medical attention while initiating oral rehydration. Optimally, rehydration should commence with reconstitution of WHO-distributed oral rehydration salts (ORS), which is available in all but the most remote areas of the world. Hydration is the mainstay of therapy, and replacement of fluids should be calibrated to match losses. ORS should be prepared with previously boiled water and consumed within 24 hours of reconstitution. IV or intraosseous hydration with Ringer lactate solution should be initiated if the patient is vomiting or in danger of hypovolemic shock. The volume needed to rehydrate a cholera patient is often underestimated; for this reason, collection and measurement of the watery stool in a bucket placed under the cholera cot is recommended.

Antibiotics are recommended for severe cases of cholera; options include¹⁵:

1. Doxycycline 300 mg orally as single dose (contraindicated in pregnancy)
2. Azithromycin 1 g orally as single dose (more effective than either erythromycin or ciprofloxacin; appropriate first-line therapy for children and in pregnancy)
3. Ciprofloxacin
4. Furazolidone 100 mg orally

In pregnancy, erythromycin 250 mg PO daily for 3 days may also be used.

PREVENTION OF DISEASES SECONDARY TO CONTAMINATED WATER

Drinking purified or treated water, good handwashing practices, and avoidance of contaminated food are essential. Travellers should be reminded not to brush their teeth with tap water and to avoid having potentially contaminated ice added to their beverages. Carbonated beverages are safe as the carbonation process is bactericidal. Community education about handwashing and treatment of water is essential. In communities lacking running water (Figure 7-4), home storage of drinking water should be in containers with protective lids. Local guidelines regarding addition of chlorine to home stored water containers should be followed.

INTESTINAL PARASITES

EPIDEMIOLOGY AND GEOGRAPHIC DISTRIBUTION

One-third of the world's population is infected with intestinal parasites, and although many parasitic infections are asymptomatic, some have serious health consequences. Especially affected are pregnant women and children, for whom hookworm-associated anemia results in maternal mortality, low-birth-weight babies, growth stunting, and impaired learning. The CDC recommends predeparture albendazole treatment as a single 600-mg dose for all refugees from sub-Saharan Africa and South Asia. While this treatment will eradicate most of the nematodes, it is insufficient for *Strongyloides stercoralis* and schistosomiasis.¹⁶

CLINICAL PRESENTATION

Abdominal pain, cramps, bloating, anorexia, anemia, fatigue, growth stunting of children, hepatomegaly (schistosomiasis).

DIAGNOSIS

Stool for ova and parasite studies (Figure 7-5). Note that these will not reliably detect *Strongyloides* or schistosomiasis; serologic testing is available for the latter. Eosinophilia is an important diagnostic clue for the presence of parasites; the finding of persistent eosinophilia warrants a careful diagnostic evaluation for parasitic infection.

TREATMENT

► Adults

Albendazole 400 mg orally as single dose will eradicate hookworm, and *Ascaris*, but not *Trichuris* in most people.¹⁷ Eradication of *Trichuris trichiura* requires 3 daily doses of albendazole or adding ivermectin to mebendazole.¹⁸

► Children 12 months to 2 years

Albendazole 200 mg orally as a single dose.¹⁹ *S. stercoralis* requires 7 days of albendazole at 400 mg twice daily. For schistosomiasis, praziquantel is effective against all species of schistosomes. Give 2 doses of 20 mg/kg PO 4 to 6 hours apart (3 doses 4 hours apart for *Schistosoma japonicum*).²⁰

PREVENTION

Preventative measures include proper management of human waste, handwashing after defecation and before cooking, and wearing shoes

FIGURE 7-4 In this Ethiopian community without running water, water is collected in Jerry cans. Thousands of women carry these heavy, filled cans for miles after filling them up from this single pipe. The local town has provided one single pipe as the water source for the community. Although there is muddy water below, the water coming from the pipe appears clear, although it is likely to harbor bacteria and parasites. (Courtesy of Richard P. Usatine, MD.)

FIGURE 7-5 *Ascaris* egg found in the stool of a child with intestinal parasites. In most developing countries *Ascaris* is treated empirically with albendazole; stool studies are not always available or may not be cost effective. (Courtesy of Richard P. Usatine, MD.)

(prevents hookworm and *Strongyloides*). WHO guidelines recommend mass treatment of school children in endemic areas with single-dose albendazole therapy once every 6 months.

MALNUTRITION

Types of malnutrition include:

- Kwashiorkor
- Marasmus
- Micronutrient deficiencies

A global shift is underway, from diseases of undernutrition to overnutrition in tandem with industrialization and advances in transportation and technology. In spite of this global shift, about a quarter of the world's preschool children demonstrate growth stunting caused by nutritional deficiencies. In resource-poor countries, adult obesity and childhood undernutrition may coexist within the same families. The causes of this seeming paradox include many factors associated with poverty: the vulnerability of preschool children to infection when sanitation is inadequate, lack of nutrition education, decreased physical activity with increasing availability of technology and transportation, and mass marketing of inexpensive, calorie-rich foods.

Two classic presentations of malnutrition in children are important to recognize because they signal a patient who is immunocompromised and vulnerable not only to infection but also to preventable developmental delay. The accompanying photographs show an emaciated child with marasmus (severe, nonedematous malnutrition caused by calorie deprivation; **Figure 7-6**), and a puffy child with kwashiorkor (severe, edematous protein energy malnutrition; **Figure 7-7**). Marasmic kwashiorkor is another descriptor, illustrating the high level of overlap in the etiology and presentation of these extreme forms of malnutrition.²¹ Whenever possible, one should avoid hospitalizing these children for nutritional rehabilitation as hospitalization will expose them to many infectious pathogens that could be lethal during their vulnerable period of “nutritional AIDS.”²²

DIAGNOSIS

Growth chart monitoring is important for earliest detection of weight loss, growth stunting, or failure to gain height and weight over time. In most resource-poor countries, growth monitoring is implemented by trained community health workers, who refer mothers for nutrition and education programs upon detecting faltering growth in children younger than the age of 5 years. Children often fail to gain weight normally after an episode of infectious diarrhea or malaria; this should be followed by a period of rapid catchup growth. If a child becomes reinfected before catchup growth is complete, the child will fall further behind on the growth curve.

Depending on the relative protein content of the diet, patients develop marasmus (calorie deprivation), characterized by emaciation and listlessness (**Figure 7-6**), or kwashiorkor, “the disease of weaning”—protein-energy malnutrition. Kwashiorkor is characterized by red discoloration of the hair (**Figure 7-8**), which is also brittle, puffy eyes, bloated bellies and pitting edema of the extremities (**Figure 7-7**). These children feel miserable and are lethargic

FIGURE 7-6 This 12 month-old Bolivian child with marasmus presented to medical attention with pneumonia. She has severe growth stunting, atrophied limbs, and looks miserable. Her presentation highlights the association between malnutrition and infection. (Courtesy of Carolina Clark.)

FIGURE 7-7 This 2-year-old child presented with classic signs and symptoms of kwashiorkor, a severe form of protein-energy malnutrition. The word *kwashiorkor*, from a Ghanaian language, refers to the sickness a child develops when it is weaned from breastfeeding. In countries with limited protein sources, newly weaned children are especially vulnerable to this disease. They present with depigmentation, red discoloration of the hair, distended abdomens, and peripheral edema. (Courtesy of Ruth Berggren, MD.)

and uninterested in food. The differential diagnosis of kwashiorkor includes nephrotic syndrome, renal failure, or right-side congestive heart failure.

PATHOPHYSIOLOGY

Childhood malnutrition, and especially kwashiorkor, may begin when a breastfeeding mother weans her child from the breast. Deprived of protective maternal antibodies and protein source, weaning infants begin sampling their contaminated environments and ingesting pathogens. Production of cytokines such as tumor necrosis factor (TNF)- α during infectious episodes suppresses appetite and impedes nutritional recovery.²²

Micronutrient deficiencies coexist,²¹ and deficiencies of vitamin A and zinc, in particular, predispose children to increased morbidity from subsequent infections. When parents are unable to replace protein requirements of weaning infants, children eat whatever locally available calorie sources (grains, cereals, bread, fruit) they can find. The poor in many developing countries lack protein sources and toddlers are frequently not prioritized when meat, milk, or eggs become available.

As a result of severe protein deficiency, hypoalbuminemia and decreased intravascular oncotic pressure lead to edema, and the classic puffy appearance of the child with kwashiorkor. For years it was believed that children with kwashiorkor are disproportionately deprived of protein, whereas children with marasmus are deprived of both protein and carbohydrate calories proportionally; it now appears there is a great deal of overlap between these two presentations of severe malnutrition.²¹

MANAGEMENT

The endless cycle of infection leading to poor appetite and weight loss leading to malnutrition and further risk of infection²² can be difficult to break unless mothers of malnourished children are taught to introduce calorie-dense weaning food supplements and snacks. Many countries have locally produced ready-to-use therapeutic foods (RUTF),²¹ offering products like Plumpy'nut, or Haiti's Nourimanba, made from peanut butter, milk powder, vegetable oil, sugar, and a vitamin mix.²³

These therapeutic foods are a useful adjunct to breaking the cycle of infection, anorexia, weight loss and malnutrition, but they are not a substitute for educating mothers about how to rehabilitate their malnourished child using locally available and affordable foods. Nonmeat protein substitutes, such as red beans, and locally available green leafy vegetables are easier for mothers to obtain than meat, cow's milk, or expensive imported food supplements.

FIGURE 7-8 Child with kwashiorkor, protein-calorie malnutrition and red hair. The red hair is a result of the kwashiorkor. (Courtesy of Richard P. Usatine, MD.)

MICRONUTRIENT DEFICIENCIES

VITAMIN A DEFICIENCY

In contrast to marasmus and kwashiorkor, growth stunting is a more subtle syndrome affecting 200 million children who are younger than the age of 5 years. A variety of micronutrient deficiencies are believed to contribute to stunting syndrome and to accompany developmental delays, reduced cognitive function, impaired immunity, and future risk of obesity and hypertension.²⁴ There are 4 micronutrient

deficiencies of global importance, each with associated clinical syndromes that should be recognized. All can be associated with growth stunting in children, who may present with abnormally short stature but relatively normal weight for height.

Vitamin A is a critical regulator of immune function, which is required for maintaining the integrity of mucosal surfaces. Vitamin A supplementation in countries with malnutrition reduces blindness (from xerophthalmia) as well as the morbidity of infectious diseases (especially measles, diarrhea, and respiratory infections). **Figure 7-9** shows a photograph of blindness caused by vitamin A deficiency. In 2009, the WHO estimated that clinical vitamin A deficiency (night blindness) and biochemical vitamin A deficiency (serum retinol concentration $<0.70 \mu\text{mol/L}$) affected 5.2 and 190 million pre-school-age children, respectively.²⁶ About 250,000 children develop blindness caused by vitamin A deficiency every year, and half of these die within 12 months of losing sight.²⁷

► Clinical presentation

The earliest presentation of vitamin A deficiency is poor night vision, which may progress to night blindness, xerophthalmia, ulceration, and scarring of the cornea, with ultimate blindness. Vitamin A deficiency is also associated with anemia, and is particularly dangerous in patients with measles, for whom mortality rates are high.

► Management

A metaanalysis of 43 trials involving 216,000 children younger than the age of 5 years who were given vitamin A supplements revealed striking reductions in mortality and morbidity. Seventeen of these trials reported a 24% reduction in mortality, and 7 trials reported a 28% reduction in mortality associated with diarrhea. Vitamin A reduced diarrhea and measles incidence. Vitamin A significantly reduces morbidity, mortality, and eye disease. Vitamin A supplements are recommended to all children who are at risk in low- and middle-income countries.²⁸ Most countries implement WHO guidelines for vitamin A supplementation synchronized with childhood vaccine schedules.

ZINC DEFICIENCY

Zinc plays a central role in cellular growth, differentiation, and metabolism. It is necessary for physical growth, GI and immune function. Many zinc studies show improved growth of children and decreased infections when supplements are given to vulnerable populations. Studies suggest that the global prevalence of zinc deficiency approaches 31%, especially in Africa, the eastern Mediterranean, and South Asia.²⁹

► Clinical presentation

The most common presentation of zinc deficiency is nonspecific and may include growth stunting, delayed sexual maturation, dermatitis, and defective immunity. Zinc deficiency is associated with decreased macrophage chemotaxis, decreased neutrophil activity, and decreased T-cell responses.²² It is widely acknowledged that zinc deficiency contributes significantly to child mortality from pneumonia, diarrhea and malaria. A rare but characteristic presentation of profound zinc deficiency is acrodermatitis enteropathica (**Figure 7-10**).

FIGURE 7-9 Child with severe xerophthalmia of the left eye secondary to vitamin A deficiency.²⁵ (Used with permission from SIGHT AND LIFE www.sightandlife.org.)

► Diagnosis

Because there is no good biomarker for zinc deficiency, diagnosis must rest on clinical suspicion and documentation of therapeutic response to supplementation.

► Management

WHO guidelines for diarrhea recommend use of low concentration ORS together with routine zinc supplementation for 10 to 14 days. Children older than age 6 months should get 20 mg daily; infants younger than age 6 months should get 10 mg daily.³⁰ Zinc supplementation decreases the duration and volume of diarrheal stools by 25% and 30%, respectively. More importantly, 14 days of zinc supplementation for a diarrheal episode reduces the incidence of diarrhea and pneumonia in the subsequent 2 to 3 months, reduces hospital admissions for diarrhea, and brings approximately a 50% reduction in noninjury deaths in the year following the treatment.³¹ Unfortunately, zinc supplementation benefits are still not widely known by healthcare workers in developing countries.³²

IRON

Iron deficiency is the most common micronutrient deficiency in the world, and 2 billion people (nearly one-third of the global population) are anemic. In resource-limited countries, iron-deficiency anemia is either caused or aggravated by malaria, intestinal parasites such as hookworm, and other chronic infections such as HIV, tuberculosis, or schistosomiasis. Iron deficiency causes enormous morbidity and contributes 20% of global maternal mortality. Because the consequences include impaired cognition and physical development, increased risk of illness in children and reduced work productivity, iron deficiency is a real barrier to economic development in resource-poor countries.³³ As with zinc and vitamin A, Iron deficiency can be detrimental to host immunity, causing decreased neutrophil chemotaxis.²²

► Interventions

The WHO has developed a 3-pronged strategy for addressing global iron deficiency: increasing iron uptake through dietary diversification and supplementation, improvement of nutritional status, and controlling infections, especially worms. In countries with significant iron-deficiency anemia, malaria, and helminth infections, these interventions can restore individual health as well as raise national productivity levels, thereby interrupting the cycle of poverty and disease.³³

IODINE

Insufficient dietary iodine can significantly lower the IQ of whole populations and is the leading preventable cause of brain damage. Although iodine deficiency is easily solved through food fortification costing 2 cents per person annually, prevalences of 60% to 90% iodine deficiency among school-age children are observed in multiple African, Asian, and eastern Mediterranean countries. There is tremendous variance of iodine deficiency within individual countries and deficiency is not linked to poor or disadvantaged districts.³⁴ Iodine deficiency occurs where the soil has low iodine content because of past glaciation or repeated leaching effects of precipitation. Food crops grown in iodine-deficient soil provide inadequate dietary iodine.³⁵

FIGURE 7-10 Acrodermatitis enteropathica caused by a zinc deficiency. Zinc supplementation is a standard recommendation from WHO in treatment of childhood diarrhea. Even children who do not have skin findings of zinc deficiency benefit with reduced duration of diarrhea and reduced mortality from all infectious causes in the ensuing months after receiving supplementation. Note the typical lesions around the (A) mouth and (B) buttocks. (Courtesy of Richard P. Usatine, MD.)

► Clinical presentation

Because iodine is required for thyroid hormone synthesis, iodine deficiency results in hypothyroidism and goiter (**Figure 7-11**). Congenital iodine deficiency results in a form of profound cognitive impairment known as *cretinism*. Other consequences include stillbirths, deaf mutism, subclinical hyper- or hypothyroidism, impaired mental function, and retarded physical development.³⁵

► Interventions

Iodine may be supplied in tablets or liquid form and taken daily; in adults, 150 µg/day is sufficient for thyroid function and an adult multivitamin typically contains 150 µg of iodine per tablet, but this is impractical. Population-based interventions should include iodization of salt, and in some developing countries, eradication of iodine deficiency has been accomplished by adding iodine drops to well water.

FIGURE 7-11 Massive goiter caused by iodine deficiency. This woman is from a country in Africa where iodine is not routinely supplemented in the diet and goiter is endemic. (Courtesy of Richard P. Usatine, MD.)

VECTOR BORNE DISEASES

MALARIA

Malaria is a protozoan infection spread by the *Anopheles* mosquito vector in endemic areas. Of the four species of malaria (*Plasmodium falciparum*, *Plasmodium ovale*, *Plasmodium malariae*, and *Plasmodium vivax*), *P. falciparum* is the most important to address, because if unrecognized and untreated, it can be rapidly fatal. Only *P. falciparum* exhibits high levels of parasitemia in blood, and it is the only type of malaria that causes sequestration of parasitized erythrocytes in microvasculature. This unique feature of *P. falciparum* is responsible for the severe end-organ damage, including renal failure, acute respiratory distress syndrome, and coma that is seen with untreated disease.³⁶

► Epidemiology and geographic distribution

There are more than 200 million cases of malaria in the world every year. According to the WHO, up to 1 million people worldwide die annually from malaria, with 89% of these deaths occurring in Africa. Most of the deaths caused by malaria occur in children younger than age 5 years. *P. falciparum*, *P. vivax*, *P. malariae*, and *P. ovale* are globally distributed in the tropics. *P. vivax* is more common in Asia, South America, Oceania, and India. *P. ovale* is found mainly in West Africa, and *P. malariae* is much less common than *P. vivax* or *P. falciparum*.

The risk for malaria varies greatly within a given country, and depends on altitude (higher altitudes have lower risk), season (greatest risk in rainy season), and urbanization (rural areas have greater risk than urban areas). Thus, travelers should be aware of these differences and plan for prophylaxis accordingly.

The CDC publication, *Health Information for International Travel*, is available online at <http://www.cdc.gov/travel/> and should be consulted for updates about regional patterns of malaria risk, as well as drug resistance and guidelines, which are subject to frequent changes.³⁷

► Clinical presentation

After a 1- to 3-week incubation period following the bite of an infected female mosquito, patients develop a nonspecific syndrome of

high fever, headache, myalgia, and shaking chills. This syndrome is frequently accompanied by nausea, vomiting, and back pain, and occasional diarrhea. Splenomegaly and anemia (related to hemolysis) are common in all 4 types of malaria.

As untreated *P. falciparum* progresses, there is a risk of cerebral malaria, which is caused by parasitized erythrocytes sequestered in the capillaries of the brain, with secondary metabolic consequences. Cerebral malaria is characterized by severe headache and altered consciousness. These patients may also develop acute respiratory distress syndrome (ARDS), hypoglycemia, acidosis, and shock in the setting of hyperparasitemia. Untreated patients with cerebral malaria ultimately progress to coma, respiratory failure, and death.³⁸

► Differential diagnosis

The initial presentation of malaria is so nonspecific that it mimics influenza (without the respiratory symptoms), enteric fever (see section on typhoid), dengue fever, rickettsial infections, brucellosis, and leishmaniasis. If hemolysis has been extensive, the patient may present with jaundice, and viral hepatitis or leptospirosis may also be on the differential diagnosis.³⁶

► Laboratory diagnosis

Malaria is usually diagnosed by light microscopy of peripheral blood smears prepared with a Giemsa, Field, or modified Wright stain (Figures 7-12 and 7-13). A thick-and-thin smear should be obtained whenever possible in every febrile patient in whom malaria is suspected, especially from febrile travelers returning from malaria endemic areas. Thin smears allow relative quantification and speciation of parasites when the parasitemia is high; thick smears are useful to rule in malaria, especially when parasitemia is low. Because a single negative smear does not rule out malaria, the test must be repeated on at least 3 occasions at 12- to 24-hour intervals.³⁹ Patients with high levels of parasitemia (>5%) have a worse prognosis, and should be considered for inpatient care.

Other diagnostic modalities include the fluorochrome acridine orange stain for fluorescence microscopy and PCR (not yet widely available but helpful for very low levels of parasitemia). Rapid antigen assays using fingerstick blood samples on cards impregnated with specific antibodies are alternative methods for laboratory diagnosis of malaria. In the United States, the U.S. Food and Drug Administration has approved the BinaxNOW Malaria test, which, although costly, is convenient for rapid field use. Unfortunately, this and other immunochromatographic strip assays are not able to determine parasite load.³⁷

► Treatment

Many cases of malaria can be treated effectively with oral medication, and parenteral therapy is reserved for severe disease or for patients who are vomiting. Before prescribing therapy, determine which species is most likely involved based on microscopy or rapid diagnostic test; consider the geographic area and local drug resistance patterns.

After the patient has been given the first dose of medication, the patient should be observed for an hour. Vomiting can be managed with metoclopramide, 10 mg orally, and if the vomiting occurs within 30 minutes, the full initial dose can be repeated. The WHO

FIGURE 7-12 A. *Plasmodium falciparum* with a banana-shaped gametocyte. Of all the species of malaria, *P. falciparum* is the most likely to cause severe morbidity and mortality. B. *Plasmodium falciparum* with chromatin in rings. (Courtesy of Richard P. Usatine, MD.)

FIGURE 7-13 Blood smear for malaria diagnosis showing *Plasmodium vivax*. Rapid field tests are now available but still more expensive than microscopy. (Courtesy of Richard P. Usatine, MD.)

recommends artemisinin-based combination treatments as first-line for uncomplicated *P. falciparum*: artemether-lumefantrine 1 dose at hours 1, 8, 24, 36, 48, and 60 based on body weight: 5 to 14 kg: 1 tablet per dose; 15 to 24 kg: 2 tablets per dose; 25 to 34 kg: 3 tablets per dose; >34 kg: 4 tablets per dose.

Other artemisinin combinations can be used as follows: artesunate plus amodiaquine, artesunate plus mefloquine, and artesunate plus sulfadoxine-pyrimethamine. The combination of choice depends on the level of resistance of the partner medication in a given region. Artemisinin and derivatives should not be given as monotherapy.

For United States-returning travelers:

- Quinine + doxycycline: quinine 10 mg/kg 3 times daily for 7 days and doxycycline twice daily for 7 days
or
- Atovaquone-proguanil: atovaquone 20 mg/kg per day, proguanil 8 mg/kg per day for 3 days.

Treatment of severe *P. falciparum*

All cases of severe malaria should be managed as medical emergencies. Give IV or IM artesunate, artemether, or quinine dihydrochloride (not available in the United States).

In the United States, give quinidine gluconate, 10 mg base/kg (up to 600 mg) in 0.9% saline by rate-controlled IV infusion over 1 to 2 hours, followed by a maintenance dose of 0.02 mg base/kg per minute with electrocardiogram (ECG) monitoring until patient can take oral drugs. Quinine and quinidine must never be given by IV bolus because of the potential for fatal hypotension.

Patients with cerebral malaria should undergo lumbar puncture to rule out bacterial meningitis (**Figure 7-14**) and their blood glucose should be checked every 4 hours because of the significant risk of hypoglycemia in severe malaria. Careful hemodynamic monitoring and management of seizures (with intravenous benzodiazepines) are essential.

► Prevention

Prevention measures are a public health priority and should include mosquito control, elimination of standing water in households and gardens, insect repellent containing at least 10% to 50% diethyltoluamide (DEET; 30% DEET provides 6 to 8 hours of protection), and permethrin-impregnated bed nets. Since 2000, prevention and control measures have reduced malaria mortality by more than 25% globally and by 33% in Africa.⁴⁰

Prevention for travelers

Choice of chemoprophylaxis depends on drug resistance patterns for *P. falciparum* in the country being visited. Generally, prophylaxis should start 1 week before arrival and should continue through 4 weeks after leaving the endemic area. In the case of atovaquone-proguanil, prophylaxis may start the day before arrival and end 7 days after departure. Drugs commonly used in prophylaxis include atovaquone-proguanil (Malarone, which is expensive in the United States), mefloquine (may cause central nervous system side effects), and doxycycline (causes photosensitivity). Chloroquine can be used only in a few areas; chloroquine-susceptible malaria is restricted to the Caribbean, Central America, and parts of the Middle East.

FIGURE 7-14 Meningitis in a child with a very rigid neck. Cerebral malaria should be in the differential diagnosis for this child. Most bacterial meningitis in children can now be prevented by vaccines frequently still not available in developing countries. (Courtesy of Richard P. Usatine, MD.)

LEISHMANIASIS

Leishmaniasis is a vector-borne disease transmitted by the sandfly. It can be divided into 2 major forms, a cutaneous form, which is the most common, and the visceral form. There is also a more rare mucocutaneous form that can cause significant facial disfigurement around the nose and mouth.

► Synonyms

Kala-azar is another name for visceral leishmaniasis.

► Epidemiology

- New World leishmaniasis is found in Mexico, Central America, and South America. Old World leishmaniasis is found in India, Africa, the Middle East, southern Europe, and parts of Asia.
- Most leishmaniasis diagnosed in the United States occurs in travelers returning from endemic areas including military personnel who served in Iraq or Afghanistan.
- Some cutaneous leishmaniasis cases acquired in the United States have been reported in Texas and Oklahoma.⁴¹
- Ninety percent of cutaneous leishmaniasis occurs in Afghanistan, Algeria, Iran, Saudi Arabia, Syria, Brazil, Colombia, Peru, and Bolivia.⁴¹
- Ninety percent of visceral leishmaniasis cases occur in parts of India, Bangladesh, Nepal, Sudan, Ethiopia, and Brazil.⁴¹

► Etiology and pathophysiology

- Leishmaniasis is caused by more than 20 species of the protozoan genus *Leishmania*.
- Leishmaniasis is transmitted to people through the bite of the sandfly.
- The intracellular amastigotes of *Leishmania* replicate within macrophages.
- The disease can also be transmitted like any bloodborne infection, but human-to-human transmission is rare.

► Risk factors

- Living in and traveling to endemic countries.
- Rural areas have a higher prevalence of disease in the endemic countries.
- Not protecting the skin from sandfly bites during the time from dusk to dawn.
- Blood transfusions, needle sharing in injection-drug users, needle-stick injuries, and congenital transmission also are all reported risk factors for visceral leishmaniasis.⁴²

► Diagnosis

Clinical features

- Six weeks after a sandfly bite, the cutaneous form may be localized to a single ulcer or nodule (Figure 7-15) or may be disseminated widely (Figure 7-16).

FIGURE 7-15 Examples of leishmaniasis on the face. Lesions emerge in the site of the sandfly bite; the nose is commonly affected as seen in the women in figures A and B from Africa. (Courtesy of Richard P. Usatine, MD.)

- After a 2- to 6-month incubation period, the visceral form can involve the liver, spleen, and bone marrow and causes systemic illness. The patient may present with fever, anemia, night sweats, weight loss and an enlarged abdomen because of hepatosplenomegaly.⁴³
- Mucocutaneous leishmaniasis affects the nose and mouth and may affect the nasal septum and palate (**Figure 7-17**). This form may occur months to years after what appears to be healing of cutaneous leishmaniasis.

Distribution

- A cutaneous form of leishmaniasis has a predilection for the nose and face (**Figure 7-15**).
- Cutaneous leishmaniasis is also commonly seen on the extremities. Note that the sandfly would generally have more access to bite the face and extremities where clothing is less likely to be a protective barrier.
- Disseminated cutaneous leishmaniasis can be seen from the head to the toes (**Figure 7-16**).

Laboratory testing

- Cutaneous leishmaniasis may be diagnosed by clinical appearance and a biopsy or a scraping of the ulcer. A Giemsa stain will demonstrate parasites in the skin smears taken from the edge of an active ulcer.⁴³ In some centers, PCR is available and is considered the method of choice.⁴⁴
- Visceral leishmaniasis is diagnosed from a blood sample or a bone marrow biopsy. Several serologic agglutination tests (direct agglutination test [DAT] or fluorescent allergosorbent test [FAST]) are highly sensitive for detection of leishmania antibodies. Culture of a bone marrow aspirate or PCR improve diagnostic yield.⁴³

► Differential diagnosis

- The differential diagnosis of cutaneous leishmaniasis includes leprosy, sarcoidosis, pyoderma gangrenosum, primary syphilis, and venous stasis ulcers.
- The differential diagnosis of visceral leishmaniasis includes malaria, typhoid fever, and lymphoma.

► Management

Nonpharmacologic

- Wound care for ulcers.

Medications

- The main drugs used to treat leishmaniasis include sodium stibogluconate (available from the CDC) and meglumine antimonate.^{45,46} Other medications used include miltefosine (the only oral drug for leishmaniasis) fluconazole and liposomal amphotericin b (this is the only drug with FDA approval for visceral leishmaniasis in the United States).^{45,46} Amphotericin b is the standard of care in India because of antimonial resistance.⁴⁴

FIGURE 7-16 Diffuse leishmaniasis in an African man with involvement from the face to the toes. The multiple nodules look like lepromatous leprosy but by skin snip testing, the diagnosis of leishmaniasis was confirmed. Figures A and B show different views of the same patient. (Courtesy of Richard P. Usatine, MD.)

Surgery

- Plastic surgery may be used to treat the disfigurement of mucocutaneous or cutaneous leishmaniasis.

PREVENTION OF VECTOR-BORNE DISEASES

Prevention is a public health priority that must include vector (mosquito and sandfly) control, elimination of standing water in households and gardens, insect repellent containing 20% to 30% DEET, and permethrin-coated bednets. Sandflies and *Anopheles* mosquitoes bite from dusk to dawn, but the *Aedes aegypti* vector of dengue fever bites any time during the day, making daytime use of mosquito repellent especially important in dengue-endemic areas.

PROGNOSIS

- Cutaneous leishmaniasis does resolve spontaneously in some cases and in other cases it may persist and resist treatments. The prognosis is related to the severity of the case and the community of the host. Even in those cases that resolve scarring is frequent.
- Visceral leishmaniasis is fatal if not diagnosed and treated.

EYES—TRACHOMA

EPIDEMIOLOGY AND GEOGRAPHIC DISTRIBUTION

Chlamydia trachomatis is the leading infectious cause of blindness, accounting for 3% of the world's blindness. Globally, 21.4 million people have trachoma, and of these, 1.2 million are blind.⁴⁷ Trachoma is associated with poor sanitation, inadequate water supply, and lack of personal hygiene. It is transmitted from person to person via unwashed fingers, flies, and close family contact (sharing of face towels and bedclothes). Trachoma is endemic in Africa (especially in the driest regions) India, South Asia, Australia, and parts of South America.

CLINICAL PRESENTATION

Patients experience inflammation of the eye with watery discharge, itching, burning, and blurry vision. Examination of the tarsal conjunctiva reveals follicles (round swellings that are paler than the surrounding conjunctiva, at least 0.5 mm in diameter). With progression, intense trachomatous inflammation develops, producing inflammatory thickening of the tarsal conjunctiva, which appears red and thickened with numerous follicles (Figure 7-18).

Eventually, trachoma causes scarring, with white lines or bands in the tarsal conjunctiva as well as trichiasis, in which eyelashes turn inward and begin to rub against the cornea, and entropion, or inward

FIGURE 7-17 Severe mucocutaneous leishmaniasis causing destruction of the nose. (Courtesy of Richard P. Usatine, MD.)

FIGURE 7-18 Trachoma causing prominent follicles on the upper eyelid in a person infected with *C. trachomatis*. Note how flipping the eyelid is needed to see the follicles under the upper eyelid. (Courtesy of Richard P. Usatine, MD.)

turning of the eyelid itself. With time, this chronic rubbing causes corneal opacity and blindness (**Figure 7-19**).

DIAGNOSIS

Although laboratory diagnostic testing is available for staining *C. trachomatis* in scrapings from the tarsal plate, most settings where trachoma is endemic do not offer this resource, and visual inspection of the everted upper eyelid must suffice. Each eye should be examined for trichiasis and corneal opacities. The upper eyelid is everted by asking the patient to look down, holding eyelashes between thumb and finger, and everting the lid using a cotton-tipped applicator. The everted lid is then checked for follicles, inflammation, and scarring. The differential diagnosis of trachoma includes allergic conjunctivitis (which can also produce follicles of the tarsal plate), and bacterial or viral conjunctivitis.

MANAGEMENT

- Azithromycin, 1 g single oral dose for adults and 20 mg/kg for children in a single dose.
- In pregnancy: erythromycin 500 mg twice daily for 7 days.
- Less effective: topical erythromycin and tetracycline.¹⁰
- In some settings, surgery is available to correct entropion and trichiasis.

PREVENTION

Preventive measures include community hygiene education, use of soap and water for washing hands and faces, and control of flies through use of ventilated improved pit (VIP) latrines. The WHO has developed the acronym "SAFE" for the global elimination of trachoma:

- S Surgery for entropion and trichiasis
- A Antibiotics for infectious trachoma
- F Facial cleanliness to reduce transmission
- E Environmental improvements such as control of disease-spreading flies and access to clean water⁴⁸

SKIN

INFECTIOUS SKIN DISEASES

Many of the skin diseases encountered in resource-limited countries are secondary to crowded living conditions and lack of clean water and soap. Scabies mites and human lice are endemic in many populations that are unable to wash frequently. If clean water is scarce it is more likely to be used for drinking and cooking than bathing. In developed countries, we take clean running water (hot and cold), soap, and shampoo for granted. In developing countries, even if water is available, it may not be accessible as warm running water for showers or baths.

When an intervention as simple as mass distribution of free soap for personal hygiene draws enormous crowds to a mobile clinic, the vastness of inequality in access to basic health measures around the world becomes painfully obvious. So although people recognize

FIGURE 7-19 Blindness caused by untreated trachoma. Although this is one of the most common causes of blindness worldwide, trachoma is easily treatable with a single dose of oral azithromycin. Prevention is achieved through better access to water and soap, together with education about the three "Fs": flies, fingers, facial hygiene. (Courtesy of Richard P. Usatine, MD.)

FIGURE 7-20 An American medical student is washing the feet of Ethiopian schoolchildren to treat skin infections and to educate them on preventive hygiene measures. (Courtesy of Richard P. Usatine, MD.)

FIGURE 7-21 Badly superinfected scabies with pustules and crusting sores on this young child's leg. (Courtesy of Richard P. Usatine, MD.)

the importance of access to soap and clean water, the absence of this luxury results in skin infections and infestations that are highly prevalent and spread from person-to-person (**Figure 7-20**).

We can divide the skin diseases into infestations, bacterial, viral, and fungal infections. All of these skin infections are covered in the dermatology section of this book. Here we highlight some cases seen in developing countries.

Scabies (see Chapter 143, Scabies) is caused by a human mite that burrows under the skin causing itching and leading to scratching. The itching and scratching may keep the person awake at night and may lead to bacterial superinfections (**Figure 7-21**). Scabies is spread by direct skin contact (**Figures 7-22** and **7-23**), shared bedding and clothing, and occasionally by fomites.

Human lice (see Chapter 142, Lice) exist as 3 separate species that are known as head lice, body lice, and pubic lice. Schoolchildren are particularly at risk for head lice, and in areas with limited head washing, the majority of kids may be infested. Body lice live on clothing and feed on the blood of their host. Body lice are more prevalent on adults that bathe rarely and wear the same unwashed clothing day after day. Pubic lice are transmitted through sexual contact and are not known to be more prevalent in developing countries. Water and hygiene issues do predispose to increased head and body lice in developing countries.

Bacterial infections of the skin (see Chapter 116, Impetigo) are ubiquitous throughout the world. Impetigo is a superficial bacterial infection that presents with honey crusts (**Figure 7-24**) or bullae. Good hygiene can prevent impetigo and therefore is not surprising that many cases of impetigo will be seen in countries that lack access to soap and clean water. Impetigo is often secondary to other skin diseases such as scabies or fungal infections that create breaks in the skin barrier function. Cases of secondarily infected scabies and tinea are seen commonly in developing countries.

Viral infections of the skin (see Chapters 123, Chickenpox; 124, Zoster; 125, Zoster Ophthalmicus; 126, Measles; 127, Fifth Disease; 128, Hand, Foot, and Mouth Disease; 129, Herpes Simplex; 130, Molluscum Contagiosum; 131, Common Warts; 132, Flat Warts; 133, Genital Warts; and 134, Plantar Warts) include herpes simplex, varicella zoster, molluscum contagiosum, and human papilloma virus infections. These infections are seen commonly in HIV-infected persons who are not receiving optimal antiretroviral therapy. In countries with a high prevalence of HIV-infected persons, a severe case of molluscum, warts, or shingles in a young person should prompt a clinician to consider HIV testing, if possible. Molluscum infections and warts are so ubiquitous throughout the world that it is important to realize that healthy people with healthy immune systems can get these infections too. Viral exanthems caused by such diseases as varicella and measles may be more prevalent in countries where vaccinations are less available.

Fungal infections of the skin (see Chapters 135, Fungal Overview; 136, Candidiasis; 137, Tinea Capitis; 138, Tinea Corporis; 139, Tinea Cruris; 140, Tinea Pedis; and 141, Tinea Versicolor) can occur from the head down to the toes. Heat, humidity, and lack of bathing are predisposing factors to fungal skin infections. Therefore tropical developing countries provide good environments for tinea capitis (**Figure 7-25**), tinea corporis, and tinea pedis.

FIGURE 7-22 A malnourished baby with marasmus is infested with scabies seen on the hands and arms. Lack of adequate nutrition also is a risk factor for many infections and diseases. The scabies infestation is a marker for scarcity of clean water; the consequences of both may be contributing to the child's irritability and poor feeding. (Courtesy of Richard P. Usatine, MD.)

FIGURE 7-23 Scabies infestation covering the mother's breast and her baby's hand. With poor access to healthcare, this infestation would likely remain untreated, and could lead to bacterial superinfection and impetigo on the baby's skin. (Courtesy of Richard P. Usatine, MD.)

MYCOBACTERIUM (LEPROSY AND TUBERCULOSIS-HIV COINFECTION)

LEPROSY

► Patient story

A young boy presents with significant changes to his face (**Figure 7-26**). The boy and his father are from rural Africa and it is obvious to the physician that the boy has lepromatous leprosy. The father is also examined and he has more subtle signs of leprosy present (several patches of hypopigmented anesthetic skin). A slit skin exam is performed on the ear lobe of the boy and many acid-fast bacilli, characteristic of *Mycobacterium leprae*, are found. The boy is started on the WHO-standard multidrug therapy using rifampin, clofazimine, and dapson. The father is also examined and treated.

► Introduction

Leprosy (Hansen disease) is caused by *M. leprae* and is still endemic in many parts of the developing world where there is poverty and poor access to clean water. At one time, persons with leprosy were called “lepers” and isolated to leper colonies because the disease was disfiguring and the communities were afraid that it was highly contagious. Current science and epidemiology tell us that leprosy is transmitted via droplets from the nose and mouth during close and frequent contact over a period of years, and not by casual contact. Thus doctors working with patients who have leprosy are at no real risk of becoming infected. Issues related to stigma and discrimination still do exist.

► Epidemiology

- There were 219,075 new cases reported in the world by 105 countries in 2011.⁴⁹
- The United States reported 173 new cases reported in 2011.⁴⁹
- Since 1990, more than 14 million leprosy patients have been cured, about 4 million from 2000 to 2010.⁵⁰

► Etiology and pathophysiology

- The clinical manifestations of leprosy depend upon the immunologic reaction to the infection. The 2 opposite ends of the spectrum consist of:
 - Lepromatous leprosy in which there is a strong antibody response and a poor cell-mediated immunity resulting in larger amounts of *M. leprae* in the tissues (**Figure 7-26**).
 - Tuberculoid leprosy in which there is a strong cell-mediated immunity and a poor antibody response resulting in less *M. leprae* in the tissues. This tends to present with hypopigmented anesthetic patches (**Figure 7-27**).
- There is also borderline leprosy in which there is a mixed cell-mediated immunity and antibody response showing features of both lepromatous leprosy and tuberculoid leprosy.
- Treatment regimens differ depending on whether the patient has paucibacillary (fewer organisms) or multibacillary leprosy. Lepromatous leprosy and borderline lepromatous leprosy are most likely to be multibacillary.

FIGURE 7-24 Impetigo caused by a bacterial infection on the buttocks of this child in Haiti. Impetigo is more prevalent when there is inadequate hygiene and lack of access to healthcare. (Courtesy of Richard P. Usatine, MD.)

FIGURE 7-25 Tinea capitis in this young boy living in a developing country. Many children live with untreated tinea capitis in developing countries because of limited hygiene resources and poor access to healthcare. (Courtesy of Richard P. Usatine, MD.)

► Risk factors

- Poverty and living in an endemic area
- Inadequate access to clean water and poor hygiene
- Living in the household of an infected person
- Eating or handling armadillos as these animals are natural hosts for *M. leprae*

► Diagnosis

Clinical features

- Facial features include leonine facies, madarosis (loss of eyebrows as seen in **Figure 7-26**), elongated and dysmorphic earlobes, and saddle-nose deformities from destruction of the nasal cartilage and bone.
- Visible skin changes include nodules in lepromatous leprosy, hypopigmented patches in tuberculoid (**Figure 7-27**) and borderline leprosy, and annular saucer-like lesions in borderline leprosy.
- Nerve involvement can cause a clawhand (flexion contractures of the fingers as seen in **Figure 7-28**), wristdrop, footdrop, Bell palsy, hammertoes, and sensory neuropathy leading to neurotropic ulcers and traumatic blisters.
- Eye involvement can cause corneal anesthesia, keratitis, episcleritis, lagophthalmos (the inability to close the eyelid completely) and blindness.
- Advanced untreated leprosy can lead to shortening and/or loss of fingers as a result of bone resorption in hands that have become anesthetic and not protected from repeated trauma (**Figure 7-29**).

Distribution

The nodules of lepromatous leprosy are mostly seen on the face and ears but can be seen in other areas. Hypopigmented patches can be seen anywhere on the body including the face.

Laboratory testing

- In obvious cases of leprosy, the slit skin exam done on the ear lobe for bacillary index is the most important test to determine if the patient has multibacillary or paucibacillary leprosy.
- In cases that are suspicious for leprosy (especially outside of endemic areas), a skin punch biopsy of a suspicious lesion is useful for finding *M. leprae* in the tissues.

► Differential diagnosis

Superficial mycoses, vitiligo, and cutaneous filariasis all cause changes in pigmentation similar to leprosy. Infiltrated lesions that resemble leprosy include those of leishmaniasis, psoriasis, and sarcoidosis.⁵²

► Management

Early diagnosis and multidrug therapy are essential to reducing the disease burden of leprosy worldwide. The WHO has supplied multidrug therapy free of cost to leprosy patients in all endemic countries.⁵¹

- Leprosy is curable and treatment in an early stage can prevent disability.
- Multidrug therapy is a combination of rifampin, dapsone, and clofazimine for multibacillary leprosy patients, and rifampin and dapsone for paucibacillary patients.

FIGURE 7-26 Lepromatous leprosy with leonine facies in a young boy. **A.** Note the loss of eyebrows called madarosis. **B.** Also note the prominent ear involvement. (Courtesy of Richard P. Usatine, MD.)

- Duration of multidrug therapy is 12 to 24 months for multibacillary and 6 months for paucibacillary patients.⁵²
- Treatment with a single antileprosy drug will always result in development of drug resistance to that drug and is therefore an unethical practice.
- Strategies to increase early access to care and provide easy-to-obtain free multidrug treatment are essential to eliminating leprosy in the world. Research on a preventive vaccine continues in tandem with *Mycobacterium tuberculosis* vaccine research.⁵³
- Comprehensive treatment of advanced cases with neuropathy should include foot and hand care to prevent further damage to these insensitive limbs.⁵²
- Surgical management for some leprosy-associated problems, such as tendon transfer to correct the clawhand, may be available in some centers.⁵⁴

TUBERCULOSIS AND HIV

► Epidemiology

Tuberculosis (TB) is a very common HIV-associated infection, and causes at least 13% of HIV-associated deaths worldwide.⁵⁵ In 2010 alone, the WHO estimated there were 1.1 million HIV-associated new cases of TB, the majority of who live in sub-Saharan Africa (**Figure 7-30**). Globally, about one-third of HIV-infected people are coinfecting with TB (at least 11 million people) (**Figure 7-31**).⁵⁶

► Pathogenesis

TB is transmitted by aerosolized respiratory droplet nuclei (see Chapter 54, Tuberculosis). Weakened cell-mediated immunity in HIV-infected individuals allows more rapid disease progression and causes higher mortality rates from TB. At the same time, untreated TB infection accelerates immunologic decline in HIV infection. Because these 2 diseases preferentially afflict populations with reduced access to medications and supportive care, the emergence of multidrug resistant TB has become an increasing threat.

► Clinical presentation

The clinical presentation of TB in an HIV-infected person with a relatively preserved immune system (CD4+ T-cell count greater than 350 cells/ μ L), is identical to that seen in HIV-negative patients. With increasing immunodeficiency, however, TB often presents atypically. Chest radiographs may not demonstrate classic findings of upper lobe fibronodular or cavitary disease, and extrapulmonary presentations (lymphadenitis, pleuritis, pericarditis, meningitis) are seen. Tuberculous lymphadenitis and cutaneous TB (designated scrofula when it affects the neck) are illustrated in **Figures 7-32, 7-33** and **7-34**.

► Diagnosis

HIV screening should be performed in all patients diagnosed with TB, and HIV-infected patients should be screened annually for *M. tuberculosis* with purified protein derivative (PPD) skin testing, chest x-ray, and/or blood test for interferon- γ release assay (IGRA) depending on availability. Patients with low CD4 cell counts (below 200 cells/ μ L) commonly have poorly reactive skin tests for TB, and thus need a careful history of exposures, review of symptoms, and monitoring of the chest x-ray for evidence of active disease, with repeat TB screening when the CD4 cell count rises above 200 cells/ μ L.

FIGURE 7-27 Multibacillary leprosy with hypopigmented patches. These patches are commonly numb due to cutaneous nerve damage from mycobacterial infection. (Courtesy of Richard P. Usatine, MD.)

FIGURE 7-28 Clawhand caused by the neurological damage of leprosy. This condition may be amenable to surgical intervention involving tendon transfer. (Courtesy of Richard P. Usatine, MD.)

FIGURE 7-29 Leprosy has caused this older man to lose his fingers but he continues to lead a productive life weaving rugs for sale at a leprosy hospital. (Courtesy of Richard P. Usatine, MD.)

► Management

Latent TB infection

HIV-positive patients with latent tuberculosis infection (LTBI) should have a chest x-ray and 3 sputum smears for acid-fast bacilli to rule out active disease. Once active TB is ruled out, isoniazid prophylaxis should be initiated regardless of age for any HIV-positive person with the following characteristics: (a) a positive diagnostic test for LTBI, or (b) a negative LTBI test but with evidence of old or poorly healed fibrotic lesions on chest x-ray, or (c) negative LTBI diagnostic test in a close contact of a person with infectious pulmonary TB.

Duration of LTBI prophylaxis: Isoniazid 300 mg daily or twice weekly for 9 months given with vitamin B₆ (pyridoxine 25 mg daily). An alternative regimen of 12 doses of once weekly isoniazid-rifapentine has recently been validated. Pyridoxine prevents isoniazid-associated peripheral neuropathy.⁵⁷

Active *M. tuberculosis* disease

Any HIV-positive patient with cough and pulmonary infiltrates should be placed in respiratory isolation until TB is ruled out by 3 separately obtained sputum smears (Ziehl-Neelsen) with cultures sent for acid-fast bacilli. This rule applies even when the chest radiograph does not demonstrate cavitory or upper lobe infiltrates. Smear-negative, culture-positive *M. tuberculosis* is not uncommon.

Treatment regimens for HIV-TB coinfecting patients are largely identical to those of TB mono-infected patients. It is important not to start antiretroviral therapy (ART) and TB therapy simultaneously, to avoid confusion about drug allergies and side effects. In addition, there is a risk of immune reconstitution syndrome (IRIS [immune reconstitution inflammatory reaction]: inflammatory response that worsens manifestations of any opportunistic infection) when ART is started too soon after initiating TB medication.

Guidelines for ART in TB coinfection are specific. If the CD4 cell count is less than 50, ART should start within 2 weeks of TB therapy. If the CD4 count is greater than 50, ART should start within 8 to 12 weeks of TB therapy. If IRIS does occur, both ART and TB treatment should be continued while managing the IRIS.⁵⁸

Directly observed therapy (DOT) for TB is strongly recommended for HIV-TB coinfecting patients.

PROVIDER AND PATIENT RESOURCES

- Traveler's Health from the Centers for Disease Control and Prevention is a comprehensive site that includes information on more than 200 international destinations, travel vaccinations, diseases related to travel, illness and injury abroad, finding travel health specialists, insect protection, safe food and water, and a survival guide—<http://wwwnc.cdc.gov/travel/>.
- The Yellow Book 2012 is available online as a reference for those who advised international travelers about health risks—<http://wwwnc.cdc.gov/travel/page/yellowbook-2012-home.htm>.
- Detailed vaccine information for travel can be obtained at the CDC website on vaccinations. This includes information on yellow fever vaccine, typhoid vaccine and routine vaccines—<http://wwwnc.cdc.gov/travel/page/vaccinations.htm>.

FIGURE 7-30 Young girl who acquired HIV at birth and now has papular pruritic eruption. One in 3 children born to HIV-infected mothers may be infected; mother-to-child transmission is preventable with simple and affordable antiviral regimens. Fortunately this girl had no signs or symptoms of tuberculosis. (Courtesy of Richard P. Usatine, MD.)

FIGURE 7-31 Young Ethiopian girl with HIV since birth who has neck swelling secondary to tuberculosis. She also has tinea capitis. HIV is a highly stigmatizing disease in most cultures, and clinicians can play an important role in mitigating community stigma by modeling compassionate care. (Courtesy of Richard P. Usatine, MD.)

- Vaccine information can be looked up by specific destination on the traveler's health website—<http://wwwnc.cdc.gov/travel/>.
- U.S. Department of State International Travel Site, including country specific information, travel alert and travel warnings—http://travel.state.gov/travel/travel_1744.html.

CONCLUSION

Medical students and health professionals are increasingly drawn to global health for reasons ranging from the desire for enhanced cultural understanding, to the mission to work for global health equity, to alleviate suffering, or to broaden medical experience beyond geographic boundaries. Whatever one's personal motivation, such experiences should never be undertaken without disciplined preparation. Medical professionals should learn in advance of their travels about the culture, language, and expressed needs and priorities of the local government and health providers and their service populations. In addition, they need to learn about the diagnoses and locally appropriate management of prevalent diseases in the population they plan to serve. Equally important, they should take appropriate preventive measures (vaccines, malaria prophylaxis) to protect their own health. Lack of personal and professional preparation can easily turn the tide from net benefit to major burdens for host country organizations. Ultimately, well-prepared medical educators and clinicians, wherever they may come from, are uniquely positioned to share knowledge that saves lives and leads to a more equitable world.

PART 3

PHYSICAL AND SEXUAL ABUSE

Strength of Recommendation (SOR)	Definition
A	Recommendation based on consistent and good-quality patient-oriented evidence.*
B	Recommendation based on inconsistent or limited-quality patient-oriented evidence.*
C	Recommendation based on consensus, usual practice, opinion, disease-oriented evidence, or case series for studies of diagnosis, treatment, prevention, or screening.*

*See Appendix A on pages 1447–1450 for further information.

8 CHILD PHYSICAL ABUSE

Jim Anderst, MD, MSCI
Ashley D. Hopkins, MD

PATIENT STORIES

CASE 1

A 1-month-old child was seen in the emergency room for bruising. Physical examination revealed bruises to the buttocks, chest, and eye. The parents reported that the child received the buttock bruise (**Figure 8-1**) after being dropped by the father, that the chest bruise was from the child's seat belt, and the eye bruise from accidentally hitting the child with an elbow while cosleeping. The social worker was consulted in the emergency room, and found no concerning "red flags" in the family. The emergency room physician felt the findings were because of inexperienced parents. The child was sent home with the parents, and the emergency room later reported the case to Children's Protective Services (CPS) in hopes of providing the family with support services. A child abuse pediatrician (CAP) was consulted by CPS to review the case the next day. The CAP requested that the child be brought back to the hospital emergently for further evaluation. A skeletal survey, including oblique views of the ribs, at that time showed a healing fracture of the eighth posterior rib (**Figure 8-2**). A head CT and liver function tests were performed to screen for occult trauma, and laboratory tests were done to evaluate for a bleeding diathesis. All were negative. Law enforcement was contacted and investigated with CPS. The child was placed in the home of a relative. Two weeks later, a repeat skeletal survey showed new bone formation over the right femur, indicating a healing fracture.

CASE 2

A 15-month-old child is brought to the emergency department by the police after a relative called 911. The child and his mother attended a family gathering where concerned relatives viewed the mother's story that the child "falls a lot" with suspicion. On examination there were many signs of physical abuse (**Figures 8-3 to 8-5**). His face was covered with bruises, especially around the right eye and cheek (**Figure 8-3**). His axilla showed signs of being gouged with fingernails (**Figure 8-4**). Although an initial skeletal survey did not show any fractures, a repeat skeletal survey and oblique views of the ribs were done 2 weeks later. The second skeletal series showed eight healing rib fractures. Repeat skeletal surveys are recommended in children younger than 4 years of age, who are confirmed or suspected victims of abuse (**Figure 8-5**). The child was admitted to the hospital and the police, hospital social workers, and CPS were notified. In the emergency department, the child was evaluated by a forensic nurse examiner trained in child-abuse photo documentation. The child was then referred to a CAP who assessed mechanisms of injuries, reexamined the child, and interpreted the initial and follow-up skeletal surveys.

FIGURE 8-1 Bruising to the left buttock noted in a 1-month-old child. Any bruising on an immobile child is highly concerning for child physical abuse. Bleeding disorders must be considered in the differential diagnosis. (Courtesy of James Anderst, MD, MS.)

FIGURE 8-2 Healing eighth posterior rib fracture in the same child from **Figure 8-1**. A skeletal survey is indicated in any child younger than 2 years of age where suspicions of physical abuse exist. (Courtesy of James Anderst, MD, MS.)

INTRODUCTION

The appropriate identification of child physical abuse is critical. Misdiagnoses in either direction (missed abuse or inappropriate diagnosis of abuse) are extremely harmful to the child and family. A careful evaluation of each case, coupled with an application of the existing scientific data on child physical abuse, may result in improved outcomes for the child and family.

EPIDEMIOLOGY

- Occurs in 9.2 per 1000 children, with highest rate of victimization in the birth to 1 year age group (20.6 per 1000).
- The Department of Health and Human Services compilation of State CPS Child Maltreatment 2010 had 3.3 million CPS reports filed in 2010, with 695,000 confirmed child victims.¹ Of these:
 - Seventy-eight percent were neglected.
 - Eighteen percent were physically abused.
 - Nine percent were sexually abused.
 - Eight percent were psychologically abused.
- Nearly 81% of victims were abused by a parent acting alone or with another person.
- Medical personnel made only 8.2% of the referrals to CPS.

RISK FACTORS

Caregiver factors associated with child abuse include the following:²⁻⁴

- Inappropriate parental expectations of the child.
- Lack of empathy toward the child's needs.
- The parent's belief in physical punishment.
- Parental role reversal.
- Caregiver's personal history:
 - Was abused during childhood.
 - Parents' rearing practices modeled.
 - Mental illness or substance abuse.

Factors specific to the child that are associated with abuse:²

- Prematurity.
- Disabilities.
- Difficult temperament.

Environmental factors associated with abuse:

- Domestic violence.
- Financial, family, or work stressors.
- Housing issues.

DIAGNOSIS

CONCERNING HISTORY⁵

- History inconsistent with child's developmental stage.
- Injuries inconsistent with history given.

FIGURE 8-3 A 15-month-old boy who has been physically abused by his mother's boyfriend for several weeks. There is bruising under both eyes, with the greatest degree of bruising seen under the right eye and on the right cheek. The boy is in the emergency department after concerned relatives called the police. (Courtesy of James Anderst, MD, MS.)

FIGURE 8-4 Same 15-month-old boy from Figure 8-3 with multiple fingernail gouges in his right axilla. Some are fresh and one appears to be older and somewhat crusted. Injuries in different stages of healing may indicate chronicity of abuse. (Courtesy of James Anderst, MD, MS.)

- History changes over time.
- History differs among witnesses.
- Delay in seeking medical care (must consider family's access to care and availability of transportation).
- Sibling blamed.
- Magical injury—No one knows how it happened.

CLINICAL FEATURES

- Bruising:⁶
 - In children who are not independently mobile.
 - Seen away from bony prominences.
 - To the face, hands, ears, buttocks, back, abdomen, and arms.
 - In the shape of an imprint of an object or hand, or a ligature (**Figure 8-6**).
 - Multiple bruises in clusters.
- Burns:⁷
 - Inconsistent with history (**Figure 8-7**).
 - Stocking/glove distribution.
 - Well-demarcated edges.
 - Symmetrical burns.
 - No splash marks.
- Fractures:⁸
 - Rib fractures.
 - Fractures in immobile children that are not attributable to birth injury.
 - Multiple fractures and/or multiple fractures of different ages.
 - Fractures in the absence of a history of trauma.
 - Any fracture that is inconsistent with the reported mechanism.
- Intracranial injury:
 - Highly variable clinical presentation, however presence of apnea, retinal hemorrhages, and/or rib fractures is more strongly associated with inflicted (versus noninflicted) intracranial injury.^{9,10}
 - Mild abusive head injury may present with isolated vomiting or fussiness.¹¹
- Oral lesions—Torn frenula, palatal petechiae, contusions, or lacerations (typically from a bottle, finger, or other object forced into the child's mouth).¹²

Failure to thrive and signs of malnutrition as a result of intentional withholding of food and/or liquids.

LABORATORY STUDIES AND IMAGING

- Concerning bruising that is not obviously abusive—Prothrombin time/partial thromboplastin time (PT/PTT), complete blood count (CBC), von Willebrand testing, factor 8 and factor 9 levels. Testing best done in collaboration with a CAP or pediatric hematologist.¹³
- Detection of occult abdominal trauma—Liver function tests (LFTs), amylase, lipase, urinalysis; CT of abdomen recommended if laboratory results are elevated or urinalysis positive for blood.¹⁴
- Detection of occult fractures—Skeletal survey (including oblique views of the ribs) in children younger than 2 years of age or nonverbal children; consider radionuclide bone scan to look for acute fractures, or a follow-up skeletal survey 2 weeks after initial presentation.¹⁵

FIGURE 8-5 Same boy from **Figure 8-3** with oblique X-ray showing healing rib fractures with callus in eight different locations as marked by the arrows. The degree of callus formation shows that these rib fractures are not new. Oblique radiographs should be requested in addition to a “skeletal survey” because lateral rib fractures are best seen with this view. (Courtesy of James Anderst, MD, MS.)

FIGURE 8-6 Linear ecchymosis on the cheek of a baby who was slapped in the face by an abusive parent. (Courtesy of James Anderst, MD, MS.)

- Detection of occult intracranial injury—CT/MR of head in all young children, even if there are no clinical signs of intracranial injury; ophthalmology examination for retinal hemorrhages.¹⁶

DIFFERENTIAL DIAGNOSIS

- Bruises and other skin findings:
 - Accidental bruises—Any bruising in an infant or precruiser is very concerning for abuse. Accidental bruising is much more common in cruising or walking children.¹⁷ Any inflicted bruising or skin markings (including those from spanking or other punishment) lasting more than 24 hours constitutes abuse.¹⁸ Ear bruising is very specific for abuse (**Figure 8-8**).¹⁹ It is not possible to accurately date bruises.²⁰ Accidental bruising is typically located on the shins, lower arms, under chin, forehead, hips, elbows, ankles, and bony prominences. Loop-like bruising is suspicious for blows with a cord or a looped belt (**Figure 8-9**).
 - Bruising with tracking of blood (subgaleal hematoma) can be seen with severe injuries to the head from violent hair pulling (**Figure 8-10**).
 - Bleeding disorders—Familial history, abnormal coagulation laboratory test results, vitamin K deficiency.
 - Other rare diseases associated with bruising—Ehlers-Danlos, Henoch-Schönlein purpura, phytophotodermatitis (skin reaction to psoralens, most commonly found in limes), osteogenesis imperfecta (brittle bones).
 - Skin discoloration—Common examples are allergic shiners (dark, puffy lower eyelids) and Mongolian spots (macular blue-gray pigmentation usually on the sacral area of normal infants, usually present at birth or appear within the first weeks of life; (see Chapter 108, Normal Skin Changes).
- Burns:
 - Accidental burns (splash marks usually seen).
 - Bullous impetigo, cellulitis, scalded skin syndrome, diaper rash.
 - Chemical burn caused by senna containing laxatives.
 - Drug reaction.
- Fractures from other diseases occurring in infants and young children:
 - Osteogenesis imperfecta—A congenital disorder with bone fragility; patients may have repeated fractures after mild trauma that heal readily. Other features seen in some cases include blue sclera, easy bruising, and deafness.
 - Rickets—Usually from vitamin D deficiency, consider in exclusively breastfed infants, dark skinned children, children with little sun exposure. The metaphyses show widening and cupping with irregular calcification as a result of poor calcification of osteoid.
- Failure to thrive from other causes including improper mixing of formula, breastfeeding difficulty, organic diseases such as cystic fibrosis, HIV, metabolic disorders, celiac disease, and renal disease.²¹

Intracranial bleeding—Other causes include accidental injury, infection, coagulation disorders, birth injury, and rare metabolic conditions (glutaric aciduria).

Cultural practices—Coining (**Figure 8-11**), cupping, moxibustion (cultural practice of burning herbs on skin).

FIGURE 8-7 Toddler being seen for a burn caused by hair straightener. The family claimed the iron fell onto the leg but further investigation seemed to indicate that the iron was applied to the child by an angry parent to control a crying child. Although the iron falling could explain the injury on the calf, it does not explain the additional injury higher up on the leg. (Courtesy of James Anderst, MD, MS.)

FIGURE 8-8 Bruising of the ear in a young boy who was physically abused by a parent. Ear bruising is rarely accidental. The additional bruising on the cheek suggests this child was hit with a hand or another object to produce the bruising seen in this photo. (Courtesy of James Anderst, MD, MS.)

MANAGEMENT

- Emergent care first; treat injuries, burns, failure to thrive accordingly.
- Careful examination of the skin and oral cavity, palpation for bony tenderness or callus formation, signs of abdominal trauma or neurologic abnormalities, ophthalmologic evaluation for retinal hemorrhages.
- Document the history provided by caregivers and physical findings accurately, including pictures.
- Consider consultation with a CAP or a family physician with additional training or expertise. Child abuse pediatrics is a new subspecialty of pediatrics requiring an additional 3 years of fellowship training.
- In cases where the injury was truly caused by an accidental mechanism, the role of neglect must be considered.
- Mandated reporting:
 - All 50 states require that all professionals who work with children report suspected child abuse and neglect.
 - Reporter of abuse is granted legal immunity.
 - Once the case is reported, further collaboration with CPS or law enforcement is usually necessary to ensure appropriate outcomes.²²

PATIENT EDUCATION

- Prevention programs:
 - Home visitation programs have been shown to reduce child abuse and child mortality.²³
 - Nursery-based prevention of abusive head trauma.²⁴
 - Specific models of primary care may reduce abuse.²⁵
 - Population-based prevention.²⁶
 - Parent–child interactive therapy (PCIT) reduces repeat abuse.²⁷

FOLLOW-UP

- If there is suspicion of fractures, obtain repeat skeletal X-ray in 2 weeks to look for evidence of healing fractures.
- Siblings of abused children should be interviewed and examined for findings concerning for abuse.
- Counseling for child and family as appropriate.
- Frequent follow-up with primary care provider to evaluate for signs of abuse and neglect.
- Report to CPS.

PATIENT RESOURCES

9 CHILD SEXUAL ABUSE

Nancy D. Kellogg, MD
Maria D. McColgan, MD

PATIENT STORY

A 12-year-old girl is being seen for chronic abdominal pain by her family physician. The physician asks the mother to step out of the room and does a complete history including the HEADSS (home life, education level, activities, drug use, sexual activity, suicide ideation/attempts) questions. The girl tearfully reports that her stepfather has been touching her in her private areas when her mother is not home. On examination with a female nurse chaperone in the room, the physician finds that the girl's hymen initially appears normal (**Figure 9-1**). However, when the girl is more carefully examined with a cotton-tip applicator, a healed posterior hymenal transection is seen (**Figure 9-2**). When the girl is asked whether any other types of sexual abuse occurred with her stepfather, she admits to repeated penile penetration. Although rare, sometimes the examination reveals more than what the child is willing to disclose about the abuse. Partial disclosures of abuse are common in children. In addition, the findings of sexual abuse tend to be subtle and are easily missed if a careful examination and special techniques are not used. Attempts are made to reassure the girl that this should never happen and that this is not her fault. Her mother is brought back into the room and after a sensitive discussion, the police are called and Child Protective Services notified.

HEADSS is an acronym that provides a framework for interviewing adolescents and children about health risks. The questions start from easiest and least sensitive to more sensitive questions that need to be asked:

H—home

E—education

A—activities

D—depression and drugs

S—sex and sexual abuse

S—suicide

EPIDEMIOLOGY

- The U.S. Department of Health and Human Services compilation of Child Protective Services (CPS) data from 48 states in 2008 indicates there were 772,000 children confirmed as victims of abuse.¹ Of these, 9% were victims of sexual abuse. Not included in these numbers are several thousand additional victims who are sexually assaulted by nonfamily members; these cases are reported to law enforcement but not CPS.
- Sexual abuse of girls occurs at much higher rate than boys: 2.3 per 1000 females versus 0.6 per 1000 males.²
- Up to 50% of abusive sexual acts involve penetration of the vagina, anus, or oral cavity, or oral–genital contact.³ In general, penetrative types of abuse are associated with poorer medical and mental health outcomes.

FIGURE 9-1 Typical appearance of the hymen and perihymenal tissues in a 12-year-old girl. Once females have entered puberty, the hymen becomes redundant with overlapping folds and is more difficult to examine for subtle signs of acute or healed injury. (Courtesy of Nancy D. Kellogg, MD.)

ETIOLOGY AND PATHOPHYSIOLOGY

Child sexual abuse occurs when a child is involved in sexual activities that he or she cannot comprehend, for which the child is developmentally unprepared and cannot or does not give consent, and/or that violate laws. All states have laws that require physicians to report a suspicion of abuse to child protection or law enforcement agencies.

Most sexual abuse involves an adult perpetrator the child knows and is expected to trust who uses deception and position of authority to gain the child's acquiescence and accommodation to the abuse;⁴ it is not unusual for the abuse to progress from less to more severe and intrusive sexual acts, and for the child to wait months or years to disclose the abuse.

DIAGNOSIS

CLINICAL FEATURES

- Child victims of sexual abuse may have behavior changes, depression, increased sexual behaviors, somatic complaints (e.g., headaches or abdominal pain, constipation, enuresis/encopresis, genital/anal pain), or may be asymptomatic.
- Child may present to a medical provider for the following reasons:
 - Child has disclosed abuse (most common); it is rare for the abuse to be witnessed. Referrals to specialized programs with clinicians trained in the assessment of child sexual abuse is recommended, and are generally accessible in most areas of the United States.
 - Caregiver suspects abuse and presents to the clinician because of behavioral or physical symptoms.
 - Child is brought for routine care and sexual abuse is suspected based on clinical findings (e.g., acute or healed genital injuries, vaginal discharge in a prepubertal child, lesions suggestive of human papillomavirus [HPV] or herpes simplex virus [HSV]).
- Recent studies show that less than 5% of child sexual abuse victims have physical examination findings indicative of penetrative trauma because the type of sexual act either does not result in tissue damage or because when tissue damage occurs, most injuries heal quickly and completely.⁵⁻⁷ In a study of 36 pregnant adolescents, only two had evidence of penetrative trauma.⁸ The medical diagnosis relies predominantly on the child's history and clinicians should remember that "normal" does not mean "nothing happened."
- Tips for doing the physical examination:
 - The anogenital inspection should utilize optimal direct light source, magnification, and appropriate examination positions and techniques.
 - Recommended examination positions include supine frogleg or lithotomy and prone knee-chest; the latter position is particularly important to confirm any posterior (between the 4 and 8 o'clock positions of the hymen in supine) defects of the hymen that are seen in supine position.
 - Various examination techniques include labial separation and traction (gently pulling the labia outward and inferiorly), gluteal lifting in prone knee-chest and using cotton-tipped applicator for separating tissues.
 - In some cases, it may help to have an assistant gently squirt a small amount of nonbacteriostatic saline onto the hymen as the

FIGURE 9-2 Hymenal cleft visible when the girl in Figure 9-1 is more carefully examined using a saline moistened cotton-tip applicator to gently separate and demonstrate the edges of the hymen. This injury was caused by sexual abuse and may have been missed without the more careful examination. (Courtesy of Nancy D. Kellogg, MD.)

FIGURE 9-3 A 10-year-old girl with an acute tear of the posterior vestibule after recent sexual assault by a stranger. The posterior vestibule is the most common location for acute penetrative trauma in females. (Courtesy of Nancy D. Kellogg, MD.)

examiner uses gentle labial traction; this procedure is used to free folded hymenal edges.

- A speculum examination and use of a cotton-tipped applicator to separate hymenal edges are traumatic procedures for prepubertal females and should not be used.
- Most findings of anal trauma can be visualized by gently spreading the anal folds.
- Physical findings concerning for abuse include:⁹
 - Abrasions or bruising of the hymen, perihymenal structures, or anus (**Figures 9-3** and **9-4**).
 - Acute or healed tear in the posterior aspect of the hymen extending to, or nearly to, the base of the hymen or further to the posterior vestibule (see **Figure 9-2**).
 - Anal bruising or lacerations (**Figure 9-5**).
 - Petechiae or bruising on the soft palate following a history of forced oral penetration.

LABORATORY TESTS AND IMAGING

- Forensic evidence collection if sexual assault occurred less than 72 to 96 hours (protocols vary from region to region) prior to clinical presentation (consider referring to an emergency department or rape crisis center skilled in performing forensic evidence collection on children).
- Approximately 5% of sexually abused children and adolescents acquire a sexually transmitted infection (STI) from the abuse⁹ (**Figure 9-6**).
- Consider STI testing in all postpubescent patients and in prepubescent children with a history of genital contact with any orifice.
- HIV, hepatitis B (if unimmunized), rapid plasma reagin (RPR) (for syphilis), cultures or nucleic acid amplification tests (with confirmation) for chlamydia, and gonorrhea and culture or polymerase chain reaction (PCR) for trichomonas.
- Culture or PCR for HSV1 and HSV2 if ulcers or vesicles are present (see **Figure 9-6**).
- Condylomata acuminata is a clinical diagnosis and biopsy is required only if lesions are atypical or resistant to treatment (molluscum contagiosum is a mimic and not sexually transmitted in children).
- Pregnancy testing in postpubescent children; consider prophylaxis (e.g., plan B) if the event occurred less than 96 hours prior to evaluation.
- Follow-up examinations 2 to 3 weeks after an acute assault to complete testing for STIs with prolonged incubation periods (especially HPV), assess resolution of injuries, and ensure emotional recovery.

DIFFERENTIAL DIAGNOSIS

In females, the following may be confused with abuse:

- Straddle injury (or other accidental trauma)—This occurs when a child falls onto an object. Bruising or lacerations to the labia majora, labia minora, or posterior fourchette may be seen. Although rare, accidental penetrating injury involving perihymenal tissues occurs, but rarely.

FIGURE 9-4 Acute hymenal hematoma in a prepubertal girl from penile penetration/contact. One reason why the considerable majority of examinations are normal may be that contact is more common than complete penetration and injuries resulting from penile contact are uncommon or are minor injuries that heal quickly and completely within days. (Courtesy of Nancy D. Kellogg, MD.)

FIGURE 9-5 Acute rectal laceration in a young boy who was sexually abused by a relative. More than 95% of anal examinations in children with a history of anal penetration are normal or nonspecific. (Courtesy of Nancy D. Kellogg, MD.)

- Anatomic variants of normal, including shallow hymenal notches, anterior hymenal clefts, midline vestibule white lines, perineal defects, and narrow hymenal rims.
- Vulvar dermatitis—This may be caused by atopy, contact irritation, or seborrhea.
- Vulvovaginitis (e.g., nonspecific vaginal flora, shigella, streptococcus, poor hygiene, candidiasis)—Complaints include vaginal irritation or itching and vaginal discharge; wet prep and/or culture may be helpful.
- Lichen sclerosus et atrophicus is a cutaneous disease not caused by sexual abuse. It may present with bleeding, bruising, and/or vulvar itching, and the examination shows subepidermal hemorrhages and/or atrophic changes with areas of hypopigmentation over the vulva, perineum, and/or anus, an “hourglass” configuration (**Figure 9-7**).
- Anogenital irritation or bleeding—Causes may be infectious (pinworms, candidiasis, group B streptococcal infection), irritative (overgrowth of normal flora, sensitivity to laundry detergent or fabric softeners, sequelae of pubic hair shaving) or anatomic (urethral prolapse, dehiscence of a labial adhesion) (**Figure 9-8**).
- Normal physiologic leukorrhea—Scant, whitish tenacious discharge in pubertal females. Wet mount is normal.

In males, the following may be confused with abuse:

- Accidental trauma (e.g., penis caught in zipper)—History should support pattern of injury. Most intentionally inflicted injuries of male genitals are physical, not sexual, abuse.
- Phimosis—Unretractable foreskin. Irritation and redness occurs as a result of trapped debris.

Additional findings that may be confused with abuse:

- Anal fissure(s), which is a superficial excoriation or tear that extends from the anal verge into the anal canal; may or may not cause pain or bleeding during bowel movements. Sometimes, but not always, associated with diarrhea or constipation.
- Perianal venous pooling is sometimes mistaken for bruising.

MANAGEMENT

- Children may present with nonspecific behavioral and physical symptoms (but no disclosure of abuse) that include chronic stomachaches or headaches, school difficulties, mood changes, and sleeping difficulties. These children should be questioned in a careful and nonleading manner about the possibility of sexual abuse. For example, the clinician may state: “I treat other children who have problems like you do with school and headaches. Some of these children have told me about things that have happened to their body or feelings that made them sad, scared, or confused. Has anything like that ever happened to you?”
- Take a history from the child if necessary to make a medical diagnosis and to determine appropriate testing, treatment, and the need to report suspected abuse to child protection or law enforcement. The clinician may opt not to take a history if the child was or will be interviewed elsewhere; in this case, information necessary to determine what type of medical assessment and testing should be obtained from other sources.

FIGURE 9-6 Herpes simplex virus (HSV) type 1 infection on the vulva of the prepubertal girl caused by sexual abuse. HSV type 1 of the genitals from sexual contact is increasing in prevalence relative to HSV type 2 infections of the genitals. (Courtesy of Nancy D. Kellogg, MD.)

FIGURE 9-7 Lichen sclerosus et atrophicus in a young girl. This is a cutaneous disease, but commonly confused with sexual abuse because of the subepidermal hemorrhages. (Courtesy of Nancy D. Kellogg, MD.)

- Ensure that the parent is not in the room for the history. Parents may be present for the physical examination.
- Use open-ended questions, such as “What happened?” or “Tell me more” as opposed to suggestive questions such as “Did Daddy touch your private parts?”
- Take careful notes and document with quotations whenever possible.
- Conduct a full physical examination including genitalia. Elicit cooperation from the child by explaining all procedures and earning his or her trust.
- Consider STI and pregnancy prophylaxis for postpubertal patients.
- Withhold STI treatment in asymptomatic prepubescent children until STI tests are confirmed positive, as the incidence of STI in asymptomatic prepubertal children is relatively low.
- Consult with an infectious disease specialist regarding HIV prophylaxis. If HIV prevalence is high in local regions, assailant risk factors are unknown or high for HIV, and if the child is evaluated within 72 hours of a high-risk exposure, then HIV prophylaxis may be appropriate.
- Examine closely for signs of physical and emotional abuse and neglect.

FOLLOW-UP

- Laws vary by state; however, all states have mandated reporting laws (see Child Welfare Information Gateway, <http://www.childwelfare.gov/>).
- All victims of sexual abuse and their families should be referred to local counseling agencies and to a Children’s Advocacy Center, or other child abuse agency if available in the community.

PATIENT EDUCATION

At well-child visits, provider should discuss touches that make children sad, scared, or confused, or that give them an “uh-oh” feeling inside, and encourage parents to reinforce these themes at home.

10 INTIMATE PARTNER VIOLENCE

Mindy A. Smith, MD, MS

PATIENT STORY

A woman who fled her abusive boyfriend is observed sitting at a table with other women in a residential chemical dependency treatment program. Her bruised face could not be missed (**Figure 10-1**). The program physician asked to speak with her and learned that her boyfriend beat her when she told him that she was voluntarily entering this program. The boyfriend was also an addict and had been physically abusive to her before. The violence escalated when she said that she needed help to stop the alcohol and drugs. She left him and did not believe that he would follow her. The program management assured her that they would not let him on the premises and would do all they could to keep her safe while she was recovering. **Figure 10-2** was taken 2 months later, when her face was healing along with her mind and spirit. She completed the 90-day program and is currently working and actively following a 12-step program.

INTRODUCTION

Intimate partner violence (IPV) is defined as an intimate partner's physical, emotional, or sexual abuse. Physical violence is the intentional use of physical force with the potential for causing death, disability, injury, or harm. Physical violence includes scratching; pushing; biting; punching; use of a weapon; and use of restraints or one's body, size, or strength against another person.¹

EPIDEMIOLOGY

IPV affects up to half of the women in the United States during their lifetime.²

- An estimated 4.9 million IPV rapes and physical assaults occur each year among U.S. women (age 18 years and older) and 2.9 million assaults occur among U.S. men. Most of these assaults include pushing, grabbing, shoving, slapping, and hitting and do not result in major injury.³ In a national telephone survey of 8000 women and 8000 men, 41.5% of the women who were physically assaulted by an intimate partner were injured during their most recent assault, compared with 19.9% of men.⁴
- Physical violence by an intimate partner can result in direct injury including death (1181 women and 329 men in 2005; Bureau of Justice, 2007), adverse psychological, and social consequences, and impaired endocrine and immune systems through chronic stress and other mechanisms.⁴
- In the family practice setting, the lifetime prevalence of abuse of women was 38.8%, with current abuse reported by 2% to 48% of women.¹

FIGURE 10-1 Bruising caused by intimate partner violence in a woman who fled her abusive boyfriend. (Courtesy of Richard P. Usatine, MD.)

FIGURE 10-2 Photograph of the woman in **Figure 10-1** taken 2 months later. Her facial and psychological wounds are healing. (Courtesy of Richard P. Usatine, MD.)

- A national survey estimated that 503,485 women and 185,496 men are stalked by intimate partners each year.⁴
- Clinicians identify only a small number of victims (1.5% to 8.5%).¹ Only approximately 20% of IPV rapes or sexual assaults, 25% of physical assaults, and 50% of stalking directed toward women are reported; fewer events against men are reported.⁴
- Between 4% and 8% of women are battered during pregnancy.⁵
- According to the National Violence Against Women Survey, more than 200,000 women age 18 years and older were raped by intimate partners in the 12 months preceding the survey.⁶
- Annually, 10 million children witness wife-battering.¹ Children may become injured themselves. One study found that children of abused mothers were 57 times more likely to have been harmed because of IPV between their parents, compared to children of nonabused mothers.⁷

RISK FACTORS

Risk factors for IPV include the following:⁸

- Individual factors—Individual factors include prior history of IPV, witnessing or experiencing violence as a child, being female, young, pregnant, less educated, unemployed, heavy user of alcohol or illicit drugs, mental health problems (e.g., depression, borderline or antisocial personality traits), and engaging in aggressive or delinquent behavior as a youth.
- For women, having a greater education level than their partner, being American Indian/Alaska Native or African American, and having a verbally abusive, jealous, or possessive partner increased risk. In addition, a risk of IPV by either a past or a new offender was almost double for women who had recently changed residence compared with those who had not moved.⁹
- For men, having a different ethnicity from their partner's increased the risk of IPV.
- Relationship factors—Relationship factors include couples with income, educational, or job status disparities or in which there is dominance and control of the relationship by one partner over the other, and marital conflict or instability.
- Community factors—Community factors include poverty and associated factors or weak community sanctions against IPV (e.g., police unwilling to intervene).

DIAGNOSIS

Asking patients directly about violence at routine visits or when presenting with clues (as below) is recommended by some for identifying patients suffering from IPV,^{1,4} **SOR**  although data are lacking that identification produces positive outcomes. It is important to use patient-centered approaches.

- Questions that may be asked include general questions about how things are going at home or more specific questions about experiences of nonviolent (e.g., insulting, threatening) or violent (e.g., grabbing, punching, beating, forced sex) abusive acts.

- Several self-administered instruments are available for detecting IPV including the Woman Abuse Screening Tool (WAST).¹⁰ In a study of screening tools, women preferred self-completed approaches (versus face-to-face), although no differences in prevalence was found for method or screening instrument.¹¹ In a predominantly Hispanic population, investigators found the Spanish version of the 4-question instrument HITS (Hurt-Insult-Threaten-Scream) to be moderately reliable with good validity compared with WAST for Spanish-speaking patients¹²; HITS has also been validated with male victims.¹³

CLINICAL FEATURES

Clues on patient history include the following:

- Chronic pain syndromes (e.g., headache, backache, stomachache, or pelvic pain).
- Depression.
- Drug and alcohol abuse.

Up to 42% of women and 20% of men who were physically assaulted as adults sustained injuries during their most recent victimization.³ Clues on physical examination:

- Physical injury—Most physical injuries are minor (e.g., contusions, lacerations, abrasions) but include broken bones, traumatic brain injury, and knife wounds (see **Figures 10-1 to 10-3**).
 - Ocular injuries can include soft-tissue injuries, corneal abrasions, orbital fractures, lens dislocation, retinal detachment, visual field loss, double vision, and blindness (see **Figure 10-1**).
 - Trauma to the mouth and lips may be accompanied by fractures, broken teeth, tongue lacerations, and altered taste and smell.
 - Injuries suspicious for abuse are those only in areas covered by clothing, injuries in different stages of healing, and injuries that show a defensive wound pattern particularly on the hands or arms.
 - Upper torso injury carries a high risk of injury to cervical spine, large vessels of the neck and chest and lungs.
- Depression or symptoms of posttraumatic stress disorder (e.g., emotional detachment, sleep disturbances, flashbacks, replaying assault in mind).
- Evidence of forced sexual assault.
- Presence of sexually transmitted infections.

MANAGEMENT

- Initial evaluation, following identification of abuse, is to assess for immediate danger to the woman and any children (e.g., Do you feel it is safe to go home tonight? Where is your partner?). If danger is perceived, assist the woman in finding a safe place to go (**Figures 10-4 and 10-5**).
- Document all findings and include photographs (with date), if possible (**Figure 10-6**).
- Develop a safety plan. This should include:
 - A safe physical location that is not known to the abuser,
 - Transportation to that location, and

FIGURE 10-3 A woman with a large craniotomy wound that was needed to evacuate her intracranial bleeding secondary to being beaten over the head with a board by her fiancé. (Courtesy of Richard P. Usatine, MD.)

FIGURE 10-4 Frontal view of the woman in **Figure 10-3** at a homeless shelter. She was putting her life back together again with the help of the shelter and the providers at the clinic. (Courtesy of Richard P. Usatine, MD.)

- A list of items to take or a packed suitcase—clothes, keys, cash, valuable documents, telephone numbers, prescriptions, something meaningful for each child.
- Address the needs of any children—30% to 40% of children are also injured physically.¹
- Data on effective intervention programs are scarce.
 - In a community intervention program in rural South Africa, providing loans to poor women combined with a participatory learning and action curriculum integrated into loan meetings every 2 weeks reduced IPV.¹⁴
 - Women residents in a domestic violence shelter showed improvement in psychological distress symptoms and less health care utilization following a social support intervention.¹⁵
 - An advocacy intervention for Chinese women who were victims of IPV did not reduce depression symptoms in a clinically meaningful way.¹⁶
 - A randomized controlled trial (RCT) of a psychobehavioral intervention for pregnant women reported reduced recurrent episodes of IPV victimization (odds ratio [OR] 0.48, 95% confidence interval [CI], 0.29, 0.80); number needed to treat = 17). Women who reported minor episodes of IPV were less likely to experience further episodes during pregnancy and women with either minor or major IPV episodes were less likely to experience further IPV postpartum.¹⁷ Early childhood visitation may also be helpful in reducing IPV.¹⁸
 - Community-provided trauma-focused cognitive behavior therapy (CBT) was effective in reducing stress symptoms and anxiety in a RCT of 7- to 14-year-old children exposed to IPV.¹⁹
 - In a Cochrane review of CBT for abusive men, only four small trials could be combined and no significant effect was found for reduced risk of violence (relative risk [RR], 0.86; 95% CI, 0.54, 1.38); the authors concluded that there were too few trials to determine effectiveness.²⁰

SCREENING AND PREVENTION

- With respect to screening, the U.S. Preventive Services Task Force and the AAFP conclude that there is insufficient evidence for or against routine screening of women for IPV.^{21,22} However, the Institute for Clinical Systems Improvement recommends domestic violence screening at preconception and first trimester and 28 week visits.²³
- In one RCT, computer screening increased detection and opportunities to discuss IPV in a busy family medicine practice.²⁴
- In an observational study of a convenience sample of 2134 patients presenting to an emergency room (25.7% screened positive), there were no harms identified from screening for IPV at 1 week post-visit and at 3 months, 35% of those screening positive reported having contacted community resources.
- With respect to outcomes, a Canadian RCT (N = 6743 English-speaking women ages 18 to 64 years) conducted in 11 emergency departments, 12 family practices, and 3 obstetrics/gynecology clinics, screening for IPV did not significantly reduce IPV recurrence (46% vs. 53% in screened vs. unscreened patients [OR, 0.82; 95%

FIGURE 10-5 A young, Hispanic mom with her baby at a clinic in a homeless shelter. She had fled her abusive husband with her child. (Courtesy of Richard P. Usatine, MD.)

FIGURE 10-6 A copy of a photograph, which the woman had in her purse, showing her black eyes after being beaten by her husband the month before. Out of fear for her life and the well-being of her child, she left her husband. (Courtesy of Richard P. Usatine, MD.)

CI, 0.32, 2.12]) or quality of life scores; loss to follow-up, however, was high (approximately 40%).²⁵

PROGNOSIS

- Many women are not ready to leave an abusive relationship for a variety of reasons. In one study, duration of abuse was less than 1 year to 5 median years, and in 5% to 3% of the instances, IPV persisted for longer than 20 years.²⁶
- Women who are abused have a higher risk of posttraumatic stress disorder, depression (1 in 6 abused women will attempt suicide¹), insomnia, nightmares, and alcohol (16-fold risk of alcohol use¹) and drug abuse (9-fold risk over nonabused patient¹).
- IPV for women also decreases the odds of completing substance abuse treatment.²⁷
- In one study, women reporting IPV in the year prior to pregnancy were at increased risk for high blood pressure or edema (adjusted OR 1.37 to 1.40), vaginal bleeding (adjusted OR 1.54 to 1.66), severe nausea, vomiting or dehydration (adjusted OR 1.48 to 1.63), kidney infection or urinary tract infection (adjusted OR 1.43 to 1.55), in addition to preterm delivery (adjusted OR 1.37), low-birth-weight infant (adjusted OR 1.17), and an infant requiring intensive care unit care (adjusted OR 1.31 to 1.33) compared with those not reporting IPV.²⁸

FOLLOW-UP

- Plan for the next visit and provide ongoing support as it often takes time for women to leave an abusive relationship.
- Monitor for depression, insomnia, nightmares, and alcohol and drug abuse.
- If pregnant, monitor for miscarriage, preterm delivery, and low birth weight.
- Children exposed to IPV also should be monitored because they are at risk of behavioral problems including aggression, anxiety/depression, and inattention/hyperactivity; especially, if maternal mental health disorders or substance abuse are also present.²⁹

PATIENT EDUCATION

- Assist patients in recognizing the cycle of abuse, that is, violence followed by remorse/apology, tension-building period (patient may experience fear, isolation, forced dependency, intermittent reward), followed by another episode of violence.
- Provide victim education and information on community resources (see Patient Resources below).
- Acknowledge that leaving may take time.
- Recovery from abuse may include shame and guilt, but often leads to an improved sense of self and self-worth.
- In a follow-up study of women exiting a shelter, women who were employed, reported higher quality of life, and had people in their

networks who provided practical help and/or were available to talk about personal matters were less likely to be re-victimized.³⁰

PATIENT RESOURCES

- National Domestic Violence Hotline connects individuals to help in their area by using a nationwide database that includes detailed information about domestic violence shelters, other emergency shelters, legal advocacy and assistance programs, and social service programs. Help is more than 170 languages, 24 hours a day, 7 days a week—www.ndvh.org. Hotline: 800-779-SAFE (7233) TTY: 800-787-3224 available for the Deaf, Deaf-Blind and Hard of Hearing. Administrative phone: 512-453-8117

11 ADULT SEXUAL ASSAULT

Mindy A. Smith, MD, MS

PATIENT STORIES

CASE 1

A 19-year-old college girl presents to the office after being raped 3 weeks ago. She went out on a date and was forced to have sex against her will. She states that she had been a virgin and that he made her bleed by penetrating her vagina with his penis. She tried to stop him, but was afraid to fight too hard because he was a strong man and was drunk. She is in tears as she tells her story. She waited so long to come in for help because she did not know where to turn. She took emergency contraception (EC) immediately, and a home pregnancy test taken last night was negative. She wants to be checked for any sexually transmitted infections (STIs). Upon examination, there is a tear of her hymen at the 5-o'clock position that has healed (**Figure 11-1**). There are no signs of infection and STI screening is performed. She is afraid to prosecute but would like to be referred to a rape-counseling program.

CASE 2

A 47-year-old woman is seen in follow-up for depression. She admits to being raped in a parking lot several months prior but did not report it to the police. She is continuing to have intrusive nightmares and flashbacks of the event. She is having difficulty concentrating at work and does not feel comfortable in social situations.

FIGURE 11-1 External genitalia of a 19-year-old college girl showing the tear of her hymen at approximately the 5-o'clock position. This was the result of date rape 3 weeks before the photograph was taken. (Courtesy of Nancy D. Kellogg, MD.)

INTRODUCTION

Sexual violence is a sex act completed or attempted against a victim's will or when a victim is unable to consent because of age, illness, disability, or the influence of alcohol or other drugs.¹ It may involve actual or threatened physical force, use of guns or other weapons, coercion, intimidation, or pressure. Sexual violence includes unwanted intercourse (completed sex act defined as contact between the penis and the vulva or penis and anus involving penetration); an attempted sex act, abusive sexual contact (intentional touching either directly or through clothing of the genitals, anus, groin, breast, inner thigh, or buttocks against a victim's will or when a victim is unable to consent); and noncontact sexual abuse, such as voyeurism, intentional exposure to exhibitionism, undesired exposure to pornography, verbal or behavioral sexual harassment, threats of sexual violence, or taking nude photographs of a sexual nature of another person without his or her consent or knowledge or of a person unable to consent or refuse.

EPIDEMIOLOGY

- Based on the National Intimate Partner and Sexual Violence Survey (NISVS; 2010) of more than 16,000 adults, nearly 1 in 5 women

(18.3%) and 1 in 71 men (1.4%) in the United States has been raped.² More than half of the women were raped by an intimate partner (see Chapter 10, Intimate Partner Violence) and 40.8% were raped by an acquaintance. Among men, more than half were raped by an acquaintance and 15.1% by a stranger.²

- Unwanted sexual contact was reported in the NISVS by 27.2% of women and 11.7% of men.²
- Lifetime stalking victimization was reported by 1 in 6 women (16.2%) and 1 in 19 men (5.2%) in the NISVS.²
- Most victims of sexual assault are young:
 - In the NISVS, most women (79.6%) experienced their first completed rape before age 25 years and 42.2% before the age of 18 years.² More than one-quarter of male victims of completed rape (27.8%) experienced their first rape before they were 11 years of age.
 - Similar findings were reported in another national survey where 60.4% of female and 69.2% of male victims were first raped before age 18 years.³ A quarter of females were first raped before age 12 years.
- In surveys of college students, annually 10% of women described a rape, 17% reported an attempted rape, 26% reported unwanted sexual coercion, and 63% experienced unwanted sexual contact.⁴
- Women in substance abuse treatment are a particularly high-risk group for having experienced violence. In one study, 89% reported a history of interpersonal violence and 70% reported a history of sexual assault.⁵
- Men are most often the perpetrators of sexual violence;² even among male victims, predominantly male perpetrators committed the rape or noncontact unwanted sexual experiences reported, and almost half of stalking victimizations of men were perpetrated by men.
- According to the FBI Uniform Crime Reports, there were an estimated 84,767 forcible rapes reported to law enforcement in 2010 or 54.2 per 100,000 women, a decrease of 5% from 2009 and 6.7% lower than 2001.⁶ Most women, however, do not report being raped to the police:
 - As in the cases presented in this chapter, most cases of sexual assault go unreported (only about 1 in 5 women report their rape to police).⁷ Reasons for failing to report include fear of reprisal, shame, fear of the justice system, and failure to define the act as rape. Furthermore, according to victim accounts in the NISVS, only 37% of the rapes reported to police resulted in the rapist being criminally prosecuted, and of those prosecuted, less than half (46.2%) were convicted of a crime.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Two types of factors are believed to contribute to sexual violence—*Vulnerability factors* that increase the likelihood that a person will suffer harm and *risk factors* that increase the likelihood that a person will cause harm. Neither vulnerability nor risk factors are direct causes of sexual violence.³

RISK FACTORS

Vulnerability factors for sexual assault, in addition to young age and female gender, include:^{8,9}

- Prior history of sexual violence.
- Being disabled (physical, psychiatric illness, or cognitive impairment).
- Pregnancy.
- Poverty, homelessness.
- Having many sexual partners or involved in sex work.
- Consuming alcohol or illicit drugs.

Risk factors for perpetration include:^{8,10}

- Alcohol and drug use.
- Childhood history of physical or sexual abuse and/or witnessed family violence as a child.
- Coercive sexual fantasies.
- Preference for impersonal sex.
- Hostility toward women.
- Association with sexually aggressive and delinquent peers.
- Family environment characterized by physical violence and few resources.
- Poverty and lack of employment opportunities.
- Societal norms that support sexual violence, male superiority, and sexual entitlement.
- Weak laws and policies related to gender equity.

DIAGNOSIS

It is recommended that patients are asked directly about violence during routine visits, when seen in the emergency department, or when presenting with substance abuse, depression, and/or physical clues (as listed below) so as to identify those who are suffering from the aftermath of sexual or physical violence.

CLINICAL FEATURES

- Approximately 33% of women and 16% of men have physical injuries as a result of a rape; 36.2% of injured women received medical treatment.¹
- Women who are raped are significantly more likely than nonraped women to experience genital injuries and STIs, and have significantly greater difficulties with aspects of reproductive/sexual functioning, including dyspareunia, endometriosis, menstrual irregularities, and chronic pelvic pain.¹¹
- Many women suffer psychological trauma following sexual assault such as posttraumatic stress disorder (PTSD) symptoms:¹
 - Immediate psychological consequences include confusion, anxiety, withdrawal, fear, guilt, intrusive recollections, emotional detachment, and flashbacks.
 - Some victims may attempt suicide after being raped (**Figure 11-2**).

FIGURE 11-2 The mutilated arm of a 26-year-old woman who was raped 5 years prior to this photograph. After being raped, she became suicidal and began cutting her arm repeatedly. The additional malformation of the arm is secondary to osteomyelitis from previous intravenous drug use. (Courtesy of Richard P. Usatine, MD.)

MANAGEMENT

NONPHARMACOLOGIC

Following a sexual assault, many women report that they thought they were going to be killed. The survivor may be terrified and unable to provide a complete history of the assault. It is important to provide support, reassurance of immediate safety, and obtain informed consent for examination, procedures, and contact of others. With permission, the clinician should contact a rape crisis worker and the police, although the survivor decides whether or not to file criminal charges; in general, notification of law enforcement is not required if the patient is an adult age 18 years or older and is not disabled, mentally ill, or elderly. In these cases, reporting is done only if the patient gives his or her consent. Injury caused by any weapon or incidents involving life-threatening assault, however, must be reported to the law enforcement agency (per statute) irrespective of reporting the sexual assault.¹²

- A guideline developed for the state of Oregon is available from the United States Department of Justice for the emergency medical evaluation of a sexual assault victim.¹² Steps in the evaluation are reviewed briefly below. A medical forensic evaluation is appropriate if the assault occurred within 84 hours of presentation. A Standard Sexual Assault Forensic Evidence (SAFE) Kit should be used for gathering forensic evidence.
- The patient should be assessed for safety and immediate mental health needs. The history includes details of the assault (e.g., date, time, location, descriptors of assailant[s]), type of bodily and sexual contact (orifice[s] penetrated, objects used), and sexual activity or bathing/washing since the assault.^{9,12} Laws in all 50 states strictly limit the evidentiary use of a survivor's previous sexual history, including evidence of previously acquired sexually transmitted diseases (STDs), as part of an effort to undermine the credibility of the survivor's testimony.¹³
- Treat traumatic injuries—Physical examination should include observations of emotional state and descriptions of clothing and stains. Gently, and with permission, examine for lacerations, abrasions, ecchymoses, and bites. A body chart may be useful for documenting the size, type, color, and location of any injuries. A genital examination should be conducted by an experienced clinician in a way that minimizes further trauma to the survivor; examination is directed by history.
- Test and treat for STI—A guideline for managing STI following sexual assault is available through the Centers for Disease Control and Prevention (CDC).¹³
 - Trichomoniasis, bacterial vaginosis (BV), gonorrhea, and chlamydial infection are the most frequently diagnosed infections following sexual assault. As the prevalence of these infections is high among sexually active women, their presence after an assault does not necessarily signify acquisition during the assault.
 - Nucleic acid amplification tests (NAATs) are recommended for *Neisseria gonorrhoeae* and *Chlamydia trachomatis*. These tests are preferred for the diagnostic evaluation of sexual assault victims, regardless of the sites of penetration or attempted penetration.¹³
 - Wet mount or point-of-care testing of a vaginal swab specimen for *Trichomonas vaginalis* infection. The wet mount also should be

examined for evidence of BV and candidiasis, especially if vaginal discharge, malodor, or itching is present.

- Collect a serum sample for immediate evaluation for HIV, hepatitis B, and syphilis, and obtain serum or urine for a pregnancy test in reproductive-aged women. Obtain toxicology and/or alcohol test if a patient has altered mental status, reports blackouts, or is concerned that he/she may have been drugged.¹²

MEDICATIONS

The following prophylactic regimen is suggested as preventive therapy:

- Hepatitis B vaccination, without hepatitis B immune globulin, is administered to sexual assault victims at the time of the initial examination if they have not been previously vaccinated. Follow-up doses of vaccine should be administered 1 to 2 and 4 to 6 months after the first dose.
- An empiric antimicrobial regimen for *Chlamydia*, gonorrhea, and *Trichomonas* is ceftriaxone 250 mg IM in a single dose **or** cefixime 400 mg orally single dose **plus** metronidazole 2 g orally (single dose) **plus** azithromycin 1 g orally (single dose) **or** doxycycline 100 mg orally twice daily for 7 days. Clinicians should counsel patients about the possible benefits and toxicities associated with these treatment regimens, such as gastrointestinal (GI) side effects.
- HIV seroconversion has occurred in persons whose only known risk factor was sexual assault or sexual abuse, but the risk is probably low (in consensual sex, the risk for HIV transmission from vaginal intercourse is 0.1% to 0.2%, for receptive rectal intercourse the risk is 0.5% to 3%, and for oral sex the risk is substantially lower).¹³
- The healthcare provider should assess available information concerning HIV-risk behaviors of the assailant(s) (e.g., a man who has sex with other men and/or injected drug or crack cocaine use), local epidemiology of HIV/AIDS, and exposure characteristics of the assault. Specific circumstances of an assault that might increase risk for HIV transmission are trauma, including bleeding, with vaginal, anal, or oral penetration; exposure to ejaculate to mucous membranes; viral load in ejaculate (e.g., multiple assailants); and the presence of an STI or genital lesions in the assailant or survivor.
- If HIV postexposure prophylaxis (PEP) is offered, the following information should be discussed with the patient: (a) the unproven benefit and known toxicities of antiretrovirals; (b) the close follow-up that will be necessary; (c) the benefit of adherence to recommended dosing; (d) the necessity of early initiation to optimize potential benefits (as soon as possible after and up to 72 hours after the assault). Providers should emphasize that PEP appears to be well-tolerated and that severe adverse effects are rare.
- Specialist consultation on PEP regimens is recommended. If the survivor and clinician decide that PEP is warranted, provide enough medication to last until the next return visit and reevaluate the survivor 3 to 7 days after initial assessment and assess tolerance of medications.¹³
- If PEP is started, perform a complete blood count (CBC) and serum chemistry at baseline (initiation of PEP should not be delayed, pending results).
- Collect samples for legal evidence. Most emergency departments have rape or sexual assault kits containing instructions for gathering material to support legal charges; all samples must be carefully

labeled and kept under supervision. Details of these procedures may be found elsewhere.¹²

- Reproductive-age female survivors should be evaluated for pregnancy, if appropriate, and offered EC if desired. Providers might also consider antiemetic medications, particularly if an EC containing estrogen is provided.
- Consider tetanus prophylaxis if skin wounds occurred and the patient is not up-to-date on tetanus immunization. Offer hepatitis vaccine if the patient has not been previously fully immunized for hepatitis B, has a negative history for hepatitis B and secretion-mucosal contact occurred during the assault.¹²
- Arrange for safety.
- Provide written information about the visit and any instructions given to the patient.

REFERRAL

- If the victim is amenable, refer for advocacy or counseling.
- If you are not the primary healthcare provider, arrange for follow-up medical care.

PREVENTION

- Women who have been physically assaulted as adolescents are at greater risk for revictimization during their college years.¹⁴ Although dating violence prevention–intervention programs have not been uniformly successful, women should be counseled about strategies for avoiding future victimization (e.g., recognition of dangerous situations, limiting use of alcohol, safety with friends). One program, Safe Dates, has been shown in a randomized controlled trial (RCT) to be effective in preventing or interrupting sexual violence perpetration.¹⁵
- Life skills and educational programs are conducted to encourage men to take greater responsibility for their actions, relate better to others, have greater respect for women, and communicate more effectively. Although not many programs have been formally evaluated, there are reports of reduced violence against women in communities in Cambodia, the Gambia, South Africa, Uganda, and the United Republic of Tanzania attributed to these programs.⁸
- Other prevention efforts include media campaigns, written materials, victim risk-reduction techniques (e.g., self-defense, awareness), men's activism groups (e.g., Men Can Stop Rape), school-based programs, and legal and policy responses (e.g., encourage reporting, broadening the definition of rape and sexual assault).^{8,16} In designing programs, information provided in documents prepared for the CDC may be useful.¹⁶

Health providers can also become involved in prevention activities at multiple levels:

- Strengthening individual knowledge and skills through skill-building programs in high schools or training bystanders to safely interrupt sexist and harassing behavior.
- Promoting community education by sponsoring activities such as plays that reinforce positive cultural norms and portray responsible sexual behavior or developing awards to recognize responsible media coverage.

- Educating other community leaders and providers, such as little league coaches, prison guards, nursing home providers.
- Fostering coalitions and networks to promote community understanding and strategies to prevent sexual violence.
- Changing organizational practices such as implementation and enforcement of sexual harassment policies in schools and workplaces, implementing environmental safety measures such as adequate lighting and emergency call boxes.
- Influencing policies and legislation such as offering comprehensive sex education programs in middle and high schools, including violence prevention.

PROGNOSIS

- More than 32,000 pregnancies result yearly from rape (approximately 5% of rapes result in pregnancy).⁸
- Chronic psychological consequences—In a metaanalysis of 17 case-control and 20 cohort studies (N = 3,162,318 participants), there was an association between sexual abuse and a lifetime diagnosis of anxiety disorder (odds ratio [OR], 3.09; 95% confidence interval [CI], 2.43 to 3.94), depression (OR, 2.66; 95% CI, 2.14 to 3.30), eating disorders (OR, 2.72; 95% CI, 2.04 to 3.63), posttraumatic stress disorder (OR, 2.34; 95% CI, 1.59 to 3.43), sleep disorders (OR, 16.17; 95% CI, 2.06 to 126.76), and suicide attempts (OR, 4.14; 95% CI, 2.98 to 5.76).¹⁷
- Chronic somatic consequences—Authors of a metaanalysis of 23 studies found associations between sexual abuse and lifetime diagnosis of functional GI disorders (OR, 2.43; 95% CI, 1.36 to 4.31), nonspecific chronic pain (OR, 2.20; 95% CI, 1.54 to 3.15), psychogenic seizures (OR, 2.96; 95% CI, 1.12 to 4.69), and chronic pelvic pain (OR, 2.73; 95% CI, 1.73 to 4.30).¹⁸ Significant associations with rape included lifetime diagnosis of fibromyalgia (OR, 3.35; 95% CI, 1.51 to 7.46), chronic pelvic pain (OR, 3.27; 95% CI, 1.02 to 10.53), and functional GI disorders (OR, 4.01; 95% CI, 1.88 to 8.57).

FOLLOW-UP

Follow-up visits provide an opportunity to (a) provide support and advocacy; (b) evaluate for resolution and healing of injury and current symptoms; (c) detect new infections acquired during or after the assault; (d) complete hepatitis B immunization, if indicated; (e) complete counseling and treatment for other STIs; and (f) monitor side effects and adherence to PEP, if prescribed.¹²

- Initial follow-up should be within 1 to 2 weeks following the assault.
- Provide ongoing support—Survivors of sexual abuse report strained relationships with family, friends, and intimate partners, including less emotional support and less frequent contact with friends and relatives.⁸ In addition, only about half of victims keep this appointment, so outreach efforts may be needed.
- Review results of tests and discuss the plan for redraw of Venereal Disease Research Laboratory (VDRL) 3 months after exposure and

HIV in 6 weeks and 3 and 6 months (if initial test results were negative).

- Long-term support, monitoring, and treatment:
 - For women suffering from PTSD, medications that may be useful include selective serotonin reuptake inhibitors and risperdal.¹⁹ Cognitive-Processing Therapy and Prolonged Exposure have been the most useful therapies for treating PTSD, depression, and anxiety in female rape victims.^{20,21} However, more than one-third of women retain the diagnosis of PTSD or drop out of treatment.²¹
 - Imagery rehearsal therapy appears useful in decreasing chronic nightmares, improving sleep quality, and decreasing PTSD symptom severity.²²

PATIENT EDUCATION

- Recovery from sexual assault is a slow process. In one study, one-third of survivors reported recovery within 1 year but one-quarter thought that they had not recovered after 4 to 6 years.²³
- Counseling, and sometimes medication, is available to help control symptoms and treat depression and PTSD and patients should be encouraged to report and seek help for continuing difficulties.

12 PTERYGIUM

Heidi Chumley, MD

PATIENT STORY

A 50-year-old man had spent most of his adult life working outdoors in southern Texas near the Mexico border. He denies any problems with his vision, but wonders what is growing on his eye and if it should be removed (**Figure 12-1**). His eyes are often dry and irritated. He is diagnosed with a pterygium and instructed that it does not need to be removed unless it interferes with his vision in the future. Liquid tears are suggested for his dry and irritated eyes. He is also instructed to wear wraparound sunglasses to avoid UV exposure and irritation from wind and dust.

INTRODUCTION

A pterygium is a generally benign growth of fibroblastic tissue on the eye of an adult with chronic UV exposure. Pterygia can be unilateral or bilateral, are usually located on the nasal side, and extend to the cornea. Pterygia often require no treatment, but can be removed surgically if they interfere with vision. Patients with dry eyes are prone to the development and progression of pterygia.

EPIDEMIOLOGY

- Pterygium most often develops between the ages 20 and 50 years.
- The frequency of pterygium increases with sun exposure and age. In a population-based study (Indonesia), it was found that the prevalence ranged from 3% (in 21- to 29-year-olds) to 18% (older than 50 years of age).¹ In rural China, the prevalence was 3.76% and also increased with age.²
- In one study carried out in Australia, it was found that sun exposure is consistently the greatest risk factor, contributing 43% of the risk.³

ETIOLOGY AND PATHOPHYSIOLOGY

- A pterygium is a proliferation of fibrovascular tissue on the surface of the eye, which extends onto the cornea.
- The etiology of pterygium is incompletely understood; however, chronic UV exposure is accepted as a causative agent. Chronic inflammation and oxidative stress may also play a role in pathogenesis.
- Pterygia have features seen in malignant tissues, such as normal tissue invasion and high recurrence rate.⁴ Pterygia can be associated with premalignant lesions.⁴

FIGURE 12-1 A nasal pterygium. (Courtesy of Richard P. Usatine, MD.)

RISK FACTORS

Risk factors are related to chronic UV exposure:

- Living in low latitude, low precipitation area.²
- Male gender.²

DIAGNOSIS

CLINICAL FEATURES

- Redness, itching, and/or irritation of the involved eyes (some are symptom free).
- Visual blurring if the pterygium grows over the visual axis. Even if not obscuring the visual axis, the pterygium can cause poor vision by leading to irregular and high astigmatism.
- Pterygia are diagnosed clinically by their distinctive appearance (**Figures 12-1 to 12-4**).

TYPICAL DISTRIBUTION

- Unilateral or bilateral.
- Nasal or nasal and temporal.
- Consider another diagnosis with a unilateral temporal distribution.

BIOPSY

Not indicated; however, excised pterygium are sent for histologic examination because of their association with premalignant lesions.⁴

DIFFERENTIAL DIAGNOSIS

- Pinguecula is a yellowish patch or nodule on the conjunctiva and does not extend onto the cornea (**Figure 12-5**).
- Conjunctivitis is conjunctival injection with discomfort and eye discharge (see Chapter 16, Conjunctivitis).
- Squamous cell carcinoma of the conjunctiva is rare. Consider carcinoma when a unilateral growth is noted on the temporal side. Also consider malignancy if there are grossly aberrant-appearing blood vessels on the surface of the eye. Patients with abnormal immune systems (e.g., cancer, HIV) are at particular risk for ocular surface malignancy.

MANAGEMENT

NONPHARMACOLOGIC

Avoid sun exposure and use UV filtering sunglasses when sun exposure is unavoidable.

MEDICATIONS

Nonprescription artificial tears and/or topical lubricating drops to soothe the inflammation. Ophthalmologists will occasionally

FIGURE 12-2 Pterygium that has grown onto the cornea but not covered the visual axis. This fibrovascular tissue has the shape of a bird's wing (literal definition of pterygium). The small vessels are prominent in this view. (Courtesy of Richard P. Usatine, MD.)

FIGURE 12-3 A pterygium that has grown over the visual axis and is interfering with this person's vision. The patient plans to undergo surgery. (Courtesy of Paul D. Comeau.)

FIGURE 12-4 Bilateral pterygia growing over the cornea. (Courtesy of Richard P. Usatine, MD.)

prescribe a short course of topical corticosteroid antiinflammatory drops when symptoms of the pterygia are more intense.

SURGICAL

- Pterygia are usually treated when they interfere with vision or when they cause significant irritation or pain (**Figure 12-3**). The standard therapy is surgical removal.
- Pterygia have a high rate of recurrence. Conjunctival autografting and an antifibrotic treatment (e.g., mitomycin-C) can be used intraoperatively to lower recurrence.⁵

ASSOCIATED RISKS

- Pterygia affect astigmatism^{6,7} and are associated with increased rates of macular degeneration; however, it is unclear whether treatment reduces this risk.
- Eyes with a pterygium or previous pterygium surgery (but not pinguecula) have a higher risk of incident late age-related maculopathy (ARM) (odds ratio [OR] 3.3, 95% confidence interval [CI], 1.1 to 10.3) and early ARM (OR 1.8, 95% CI, 1.1 to 2.9).⁸

PREVENTION

Sunglasses with 100% UV protection should be used by everyone to protect the eyes from UV damage (**Figure 12-6**). Sunglasses should fit close to the eye to block scattered or reflected light in addition to direct light.⁹

PROGNOSIS

Most pterygia do not require surgical treatment. Pterygia that interfere with vision and are removed have a high chance of recurrence.

FOLLOW-UP

No specific follow-up is needed; however, consider monitoring vision during annual examinations because of the increased risk of age-related macular degeneration.

PATIENT EDUCATION

Wraparound sunglasses are helpful to avoid UV exposure and irritation from wind and dust. Liquid tears are suggested for dry and irritated eyes.

13 HORDEOLUM AND CHALAZION

Heidi Chumley, MD

PATIENT STORY

A 35-year-old woman presented with a tender nodule on the upper eyelid along with crusting and erythema to both eyelids (**Figure 13-1**). The upper eyelid had a large external hordeolum. When the lower eyelid was inverted, an internal hordeolum was also present. The physician recommended that she apply warm moist compresses to her eyelids 4 times a day. Her hordeola resolved within 7 days.

INTRODUCTION

A hordeolum is an acute painful infection of the glands of the eyelid, usually caused by bacteria. Hordeola can be located on the internal or external eyelid. Internal hordeola that do not completely resolve become cysts called chalazia. External hordeola are commonly known as styes.

SYNONYMS

Stye (external hordeolum).

EPIDEMIOLOGY

- Unclear incidence or prevalence in the United States, but often stated to be more common in school-age children and adults 30 to 50 years old.
- In one study of school-age children in Brazil, the prevalence of chalazion was found to be 0.2% and that of hordeolum was 0.3%.¹

ETIOLOGY AND PATHOPHYSIOLOGY

HORDEOLUM (ACUTELY TENDER NODULE IN THE EYE)

- Infection in the meibomian gland (internal hordeolum), often resolves into a chalazion (**Figure 13-1**).
- Infection in the Zeiss or Moll gland (external hordeolum) (**Figures 13-2 and 13-3**).
- *Staphylococcus aureus* is the causative agent in most cases.

CHALAZION

- Meibomian gland becomes blocked, often in a patient with blepharitis.
- Blocked meibomian gland's duct releases gland contents into the soft tissue of eyelid.

FIGURE 13-1 External hordeolum (black arrow) and an internal hordeolum (white arrow) (Courtesy of Richard P. Usatine, MD.)

FIGURE 13-2 External hordeolum on upper lid with surrounding erythema. (Courtesy of Richard P. Usatine, MD.)

- Gland contents cause a lipogranulomatous reaction (**Figure 13-4**).
- Reaction can cause acute tenderness and erythema, which then resolves into a chronic nodule (**Figure 13-5**).

RISK FACTORS

- Hordeolum: *S. aureus* blepharitis, previous hordeolum.
- Chalazion: Seborrheic blepharitis and rosacea.

DIAGNOSIS

- Chalazion and hordeolum are clinical diagnoses.
- Chalazion is a nontender nodule on the eyelid.
- Hordeolum
 - Tenderness and erythema localized to a point on the eyelid (**Figures 13-1 to 13-3**).
 - Conjunctival injection may be present.
 - Fever, preauricular nodes, and vision changes should be absent.
 - Laboratory tests are generally not indicated.

DIFFERENTIAL DIAGNOSIS

- Hydrocystoma—Benign cystic lesion that grows on the edge of the eyelids and is filled with clear fluid (**Figure 13-6**).
- Xanthelasma—Yellowish plaques, generally near medial canthus (see Chapter 223, Hyperlipidemia).
- Molluscum contagiosum—Waxy nodules with central umbilication; generally multiple (see Chapter 130, Molluscum Contagiosum).
- Sebaceous cell carcinoma—Rare cancer seen in middle-age and elderly patients; difficult to distinguish from recurrent chalazion or unilateral chronic blepharitis without biopsy.
- Basal cell carcinoma—Pearly nodule, often with telangiectasias or central ulceration; more common on lower medial eyelid (see Chapter 170, Basal Cell Carcinoma).

MANAGEMENT

- Hordeolum (internal):
 - No studies of nonsurgical interventions (compresses, lid scrubs, antibiotics, steroids) met criteria for inclusion in a Cochrane study. No evidence for or against nonsurgical interventions for acute internal hordeolum.¹ **SOR A**
 - Treat as described below for external hordeolum.
- Hordeolum (external):
 - Warm soaks, 3 to 4 times a day for 15 minutes, will elicit drainage in most cases. **SOR C**
 - Topical antibiotics (e.g., bacitracin ophthalmic ointment) may be beneficial for recurrent or spontaneously draining hordeolum. **SOR C**
 - Cases that do not respond to warm soaks or that are extremely painful and swollen may be incised and drained with a small

FIGURE 13-3 External hordeolum with visible purulence and the normal contour of the eyelid is disrupted. (Courtesy of Richard P. Usatine, MD.)

FIGURE 13-4 Chalazion viewed from internal eyelid showing the yellow lipogranulomatous material. (Courtesy of Richard P. Usatine, MD.)

FIGURE 13-5 Chalazion present for 4 months with minimal symptoms but cosmetically unappealing. (Courtesy of Richard P. Usatine, MD.)

incision using a #11 blade. Make the incision on either the internal or external eyelid depending on where the hordeolum is pointing. A chalazion clamp can be used to protect the globe from damage. **SOR B**

- Antibiotics do not provide benefit after incision and drainage.³ **SOR B**
- Systemic antibiotics are usually not needed unless patient has preseptal cellulitis. **SOR C**
- Chalazion
 - Can be treated conservatively with lid hygiene and warm compresses. Warm compresses can be applied 2 to 3 times daily but may take weeks to months to work. **SOR C**
 - One study demonstrated a 58% response rate of 1% topical chloramphenicol with warm compresses.³ **SOR B**
 - Higher percentages of resolution can be achieved with either incision and curettage or injection with steroid (e.g., 0.3 mL triamcinolone acetonide) (80% to 92%).^{4,6} **SOR B** The chalazion is usually drained from the internal eyelid using a chalazion clamp to protect the globe. After anesthetizing the area, a #11 blade is carefully used to open the chalazion. A chalazion curette helps to scoop out the lipogranulomatous material. No suturing is needed.
 - A study of 136 patients compared triamcinolone injection, incision and curettage, and warm compresses, and found resolution rates of 84%, 87%, and 46%, respectively.⁶ **SOR B**
 - One study demonstrated a better response to incision and curettage in the following situations: patients 35.1 years of age or older, with lesion duration equal to or greater than 8.5 months and size equal to or greater than 11.4 mm.⁵ **SOR B**

REFERRAL

Refer to an ophthalmologist if the hordeolum or chalazion is interfering with vision and not responding to therapy. If a surgical intervention is needed and you lack experience doing such a procedure, refer to ophthalmology.

PREVENTION

Eyelid hygiene, keeping the area around the eyelid clean, may prevent hordeola.

PROGNOSIS

Chalazia can persist for years if untreated. Some patients are prone to recurrence of hordeola and chalazia.

FOLLOW-UP

A hordeolum with significant purulence and swelling should be reevaluated in 2 to 3 days or referred to an ophthalmologist. Warm compresses are slow to work for a chalazion, so follow-up should be no sooner than 1 month if nonsurgical treatment is prescribed.

FIGURE 13-6 Hidrocystoma showing telangiectasias. The cyst was easily resected and the fluid was clear. (Courtesy of Richard P. Usatine, MD.)

PATIENT EDUCATION

Hordeolum commonly responds to warm soaks and topical antibiotics. It often recurs and can develop into a chronic chalazion, which may need to be treated with surgical removal or a steroid injection.

14 SCLERAL AND CONJUNCTIVAL PIGMENTATION

Heidi Chumley, MD

PATIENT STORY

A 40-year-old white man came to see his physician about a brown spot in his eye (**Figure 14-1**). He noticed this spot many years ago, but after recently reading information on the Internet about brown spots in the eye, became concerned about ocular melanoma. He thinks the spot has changed in size. He denies any eye discomfort or visual changes. He was referred for a biopsy, and the pathology showed a benign nevus that did not require further treatment.

INTRODUCTION

Scleral and conjunctival pigmentation is common and usually benign. Nevi can be observed and referred if they change in size. Primary acquired melanosis (PAM) must be biopsied because PAM with atypia has malignant potential, whereas PAM without atypia does not. Conjunctival melanoma is rare, but deadly.

EPIDEMIOLOGY

Although there is little information on the prevalence of ocular pigmentation other than physiologic (racial) melanosis, in a study of pigmented lesions referred for biopsy, investigators reported that 52% were nevi, 21% were PAM, and 25% were melanoma.¹

- Scleral and conjunctival nevi (see **Figures 14-1** and **14-2**) are the most common cause of ocular pigmentation in light-skinned races. The pigmentation is generally noticeable by young adulthood, and is more common in whites.²
- Physiologic (racial) melanosis (**Figure 14-3**) is seen in 90% of black patients.³ It can be congenital, and often presents early in life.
- PAM (**Figure 14-4**) is generally noted in middle-aged to older adults,^{4,5} and is also more common in whites.
- Conjunctival melanoma (**Figures 14-5** to **14-7**) is rare, occurring in 0.000007% (7 per 1,000,000) of whites; it is even less common in other races.⁵

ETIOLOGY AND PATHOPHYSIOLOGY

The etiology of scleral or conjunctival nevi is not well understood. Racial melanosis is genetically determined. Conjunctival melanoma can arise from PAM with severe atypia, nevi, or de novo.^{6,7}

FIGURE 14-1 Scleral nevus. Unilateral localized distinct area of dark pigmentation on sclera. (Courtesy of Paul D. Comeau.)

FIGURE 14-2 Conjunctival nevus. Unilateral localized distinct area of dark pigmentation on conjunctiva. (Courtesy of Paul D. Comeau.)

RISK FACTORS

- In non-Hispanic whites, the incidence of conjunctival melanoma increases as latitude decreases.⁸
- Fair-skinned individuals are at higher risk for conjunctival melanoma.

DIAGNOSIS

Definitive diagnosis of pigmented ocular lesions is by biopsy.

CLINICAL FEATURES

- Benign nevi and physiologic or racial melanosis are stable over time, whereas PAM and melanoma change.
- Intrinsic cysts are common in conjunctival nevi and rare in racial melanosis, PAM, and melanoma. Seen with slit-lamp biomicroscopy.⁹

TYPICAL DISTRIBUTION

- Physiologic melanosis is typically bilateral and symmetrical.
- Nevi, PAM, and melanoma are typically unilateral; however, one study found that 13% of PAM cases were bilateral.⁷

LABORATORY TESTING

- None indicated, other than biopsy.

IMAGING

- Often not helpful, as diagnosis is made by biopsy.
- Anterior segment coherence tomography is being studied as a diagnostic aid for conjunctival nevus because cysts are detectable. In one study, there was 100% positive predictive value (PPV) but only 60% negative predictive value (NPV).⁹

BIOPSY

- Eighty-seven percent of biopsy-proven nevi do not change over time.⁴
- Features seen more commonly in malignancy: ulceration, hemorrhage, change in color, and formation of new vessels around the lesion.
- Pathologic factors of conjunctival melanoma with a higher mortality rate include increased tumor thickness, location on the palpebral, caruncular or forniceal conjunctiva, increased mitotic activity, lymphocytic invasion, and association with PAM.¹⁰

DIFFERENTIAL DIAGNOSIS

Pigmented areas on the sclera or conjunctiva include the following:

- Benign nevi—Unilateral and stable over time (see **Figures 14-1** and **14-2**).
- Physiologic or racial melanosis—Bilateral and symmetric, most common circumlimbally, and relatively consistent throughout patient's life (see **Figure 14-3**).

FIGURE 14-3 Physiologic (racial) melanosis. Flat conjunctival pigmentation present bilaterally starting at the limbus and most prominent in the interpalpebral zone is likely to be racial melanosis in a darkly pigmented patient. (Courtesy of Paul D. Comeau.)

FIGURE 14-4 Primary acquired melanosis (PAM). Multiple unilateral indistinct areas of dark pigmentation. (Courtesy of Paul D. Comeau.)

FIGURE 14-5 Conjunctival melanoma. Unilateral, nodular lesion with irregular contours and colors, and surrounded by hyperemic vessels. (Courtesy of Paul D. Comeau.)

- PAM—Typically unilateral, often multifocal indistinct areas of dark pigmentation, and can progress to malignancy over time (**Figure 14-4**). This term is used clinically when the histology is not known.
- Secondary acquired melanosis—Seen with hormonal changes or after trauma to the conjunctiva with irradiation, chemical irritation, or chronic inflammation.
- Conjunctival melanoma—Unilateral, nodular, with variegated color and size changes (**Figures 14-5 to 14-7**).
- Alkaptonuria—Rare disease accompanied by dark urine and arthritis.
- Nevus of Ota (also known as oculodermal melanocytosis)—Blue-gray scleral pigment involving the periorbital skin as well (**Figure 14-8**). It is more common in the Asian population but can be seen in any population. It can also be bilateral. Most importantly these persons should be followed by an ophthalmologist because they are at higher risk for glaucoma and possibly melanoma.

MANAGEMENT

- Racial melanosis and nevi are two lesions that can be monitored for changes without a biopsy.
- Refer any changing pigmented lesion in the eye to a specialist who can perform a biopsy.
- Biopsy-proven PAM without atypia does not require excision, but must be monitored for stability. **SOR C**
- Melanosis with atypia is generally removed with large margins because of its potential for conversion into melanoma.⁴ **SOR C**
- The primary treatment for conjunctival melanoma is surgical removal. Cryotherapy, radiotherapy, and chemotherapy may be used as adjunct therapy. **SOR C**

PREVENTION

To decrease risk of conjunctival melanoma, use sunglasses that protect the eye from UV radiation. **SOR C**

PROGNOSIS

In one study, PAM without atypia or with mild atypia did not progress into melanoma. Thirteen percent of PAM cases with severe atypia did progress. The risk of melanoma increases as PAM covers more of the iris circumference (**Figure 14-4**).⁶ In one study, conjunctival melanoma arose from PAM, nevi, and de novo. Melanoma arising de novo had a worse prognosis. Other bad factors were fornix location and nodular tumor.⁷

FOLLOW-UP

Follow-up is based on the type of lesion. Nevi and physiologic melanosis that have not changed can be monitored without biopsy. PAM requires close follow-up because of its potential conversion to melanoma. Patients with nevus of Ota should be monitored for glaucoma and melanoma.

FIGURE 14-6 Early photo of conjunctival melanoma with irregular borders and variations in color. (Courtesy of Paul D. Comeau.)

FIGURE 14-7 Conjunctival melanoma, 1 year after the previous photo, in a patient who initially declined treatment. (Courtesy of Paul D. Comeau.)

PATIENT EDUCATION

Most pigmentation in the eye is benign and does not change over time. Discuss the importance of reporting any changing pigmented lesion, even in the eye.

15 CORNEAL FOREIGN BODY AND CORNEAL ABRASION

Heidi Chumley, MD

PATIENT STORY

A 28-year-old man felt something fly into his eye while he was using a table saw without wearing protective eye gear. He presented with pain, tearing, photophobia, and thought that something was still in his eye. On examination with a slit lamp, the physician noted that he had a wood chip that had penetrated the cornea (**Figures 15-1 and 15-2**). He was referred to an ophthalmologist who successfully removed the foreign body. He was treated with a short course of topical NSAIDs for pain relief, and had complete healing.

INTRODUCTION

Corneal abrasions are often caused by eye trauma and can cause an inflammatory response. Corneal abrasions are detected using fluorescein and a UV light. A corneal foreign body can be seen during a careful physical examination with a good light source or slit lamp. Nonpenetrating foreign bodies can be removed by an experienced physician in the office using topical anesthesia. Refer all penetrating foreign bodies to an ophthalmologist.

SYNONYMS

Corneal abrasion is sometimes referred to as a corneal epithelial defect.

EPIDEMIOLOGY

- Corneal abrasions with or without foreign bodies are common; however, the prevalence or incidence of corneal abrasions in the general population is unknown.
- Corneal abrasions accounted for 85% of closed-eye injuries in adults presenting to an emergency department.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- The cornea overlies the iris and provides barrier protection, filters UV light, and refracts light onto the retina.
- Abrasions in the cornea are typically caused by direct injury from a foreign body, resulting in an inflammatory reaction.
- The inflammatory reaction causes the symptoms and can persist for several days after the foreign object is out.

FIGURE 15-1 Wood chip is visible in the cornea on close inspection of the eye. (Courtesy of Paul D. Comeau.)

FIGURE 15-2 Slit-lamp examination reveals this wood chip has penetrated the cornea. (Courtesy of Paul D. Comeau.)

RISK FACTORS

- Those with occupations such as metal workers, woodworkers, miners, and landscapers have an increased risk of corneal injuries from foreign bodies.²
- Participating in sports such as hockey, lacrosse, or racquetball raises the risk of corneal abrasions from ocular trauma.²
- Ventilated neonates (as a result of mask pressure on the orbit) or sedated patients (as a result of disruption of the blink reflex, and subsequent corneal exposure) are at increased risk for corneal abrasions.²

Contact lenses, especially soft extended wear, increase the risk of developing an infected abrasion that ulcerates.²

DIAGNOSIS

CLINICAL FEATURES

History and physical

- History of ocular trauma or eye rubbing (although corneal abrasions can occur with no trauma history).
- Symptoms of pain, eye redness, photophobia, and a foreign-body sensation.
- Foreign body seen with direct visualization or a slit lamp (**Figure 15-3**).
- Fluorescein application demonstrates green area (which represents the disruption in the corneal epithelium) under cobalt-blue filtered light (**Figure 15-4**).
- History of contact lens wear.
- History of ocular or perioral herpes virus infection.

LABORATORY TESTING

- Culture if an infection is suspected.

IMAGING

- If physical examination is equivocal, imaging may be useful to determine if a foreign body has perforated the cornea. An object that has fully perforated the cornea has passed through the cornea and will be located in the anterior segment or posterior segment of the eye, making it difficult to see without imaging technology.
- CT or spiral CT can detect nonmetallic and metallic foreign bodies.
- A metallic foreign body can be seen on an orbital radiograph. Avoid MRI if the history suggests the foreign body may be metallic.

Ultrasound and ultrasound biomicroscopy can also visualize intra-ocular foreign bodies and may be useful in some cases.

DIFFERENTIAL DIAGNOSIS

- Uveitis or iritis—Usually unilateral 360-degree perilimbal injection, eye pain, photophobia, and vision loss (see Chapter 18, Uveitis and Iritis).

FIGURE 15-3 Metallic foreign body with rust ring within the corneal stroma and conjunctival injection. (Courtesy of Paul D. Comeau.)

FIGURE 15-4 Fluorescein stains green, indicating corneal abrasion. (Courtesy of Paul D. Comeau.)

- Keratitis or corneal ulcerations—Diffuse erythema with ciliary injection often with miosis; eye discharge; pain, photophobia, and vision loss depending on the location of ulceration (**Figures 15-5** and **15-6**). There is often a history of trauma, herpes simplex virus (HSV), or contact lens wear. Patients should see an ophthalmologist urgently.
- Conjunctivitis—Conjunctival injection; eye discharge; gritty or uncomfortable feeling; no vision loss, history of respiratory infection, or contacts with others who have red eyes (see Chapter 16, Conjunctivitis).
- Acute-angle closure glaucoma—Cloudy cornea and scleral injection; eye pain with ipsilateral headache; severe vision loss, acutely elevated intraocular pressure (see Chapter 19, Glaucoma).

MANAGEMENT

NONPHARMACOLOGIC

- Confirm diagnosis with fluorescein and a UV light (for abrasion) if no foreign body is readily visible (see **Figure 15-4**).
- Carefully inspect for a foreign body. Invert the upper eyelid for full visualization. Slit-lamp visualization may be needed to determine if the cornea has been penetrated (see **Figure 15-2**).
- Remove (or refer for removal) nonpenetrating foreign bodies. Apply a topical anesthetic, such as proparacaine or tetracaine. Remove with irrigation, a wet-tipped cotton applicator, or a fine-gauge needle.
- Remove contact lenses until cornea is healed.³ **SOR C**
- Avoid patching in corneal abrasions smaller than 10 mm; it does not help.⁴ **SOR A**

MEDICATIONS

- Prescribe ophthalmic NSAIDs for pain if needed.⁵ **SOR A**
- Consider topical antibiotics. **SOR C** Chloramphenicol ointment reduced the risk of recurrent ulcer in a prospective, nonplacebo, controlled trial.⁶ Although chloramphenicol is rarely used in the United States, other ophthalmic antibiotics, such as erythromycin ointment, are used for corneal abrasions. **SOR C**

REFERRAL

- Refer penetrating foreign bodies to an experienced eye surgeon.

PREVENTION

Eye protection should be worn for high-risk occupational and recreational activities.

PROGNOSIS

Prognosis is generally good. Development of infection or a rust ring worsens prognosis.

FIGURE 15-5 Small corneal ulcer in the visual axis. (Courtesy of Paul D. Comeau.)

FIGURE 15-6 Larger corneal ulcer partially obscuring the visual axis. (Courtesy of Paul D. Comeau.)

FOLLOW-UP

See all patients in 24 hours for reassessment. If there is no improvement, look for an initially overlooked foreign body or a full-thickness injury. Don't hesitate to refer to ophthalmology if patient is not improving.

PATIENT EDUCATION

- Advise patients in specific professions (e.g., woodworking, metal working) and those who play sports, such as racquetball or hockey, to wear eye protection for primary prevention.
- Advise patients with corneal abrasions that healing usually occurs within 2 to 3 days, and they should report persistent pain, redness, and photophobia.
- Patients should be advised not to sleep in contact lenses, even if labeled "extended wear."

PATIENT RESOURCES

16 CONJUNCTIVITIS

Heidi Chumley, MD
Richard P. Usatine, MD

PATIENT STORY

A 35-year-old woman presents with 2 days of redness and tearing in her eyes (**Figure 16-1**). She has some thin matter in eyes, but neither eye has been glued shut when she awakens. She does not have any trouble seeing once she blinks to clear any accumulated debris. Both eyes are uncomfortable and itchy, but she is not having any severe pain. She does not wear contact lenses and has not had this problem previously. The patient was diagnosed with viral conjunctivitis and scored -1 on the clinical scoring system (see “Diagnosis” below). She was instructed about eye hygiene and recovered in 3 days.

INTRODUCTION

Conjunctivitis, inflammation of the membrane lining the eyelids and globe, presents with injected pink or red eye(s), eye discharge ranging from mild to purulent, eye discomfort or gritty sensation, and no vision loss. Conjunctivitis is most commonly infectious (viral or bacterial) or allergic, but can be caused by irritants. Diagnosis is clinical, based on differences in symptoms and signs.

SYNONYMS

Pink eye.

EPIDEMIOLOGY

- Infectious conjunctivitis is common and often occurs in outbreaks, making the prevalence difficult to estimate.
- In the United States, the estimated annual incidence rate for bacterial conjunctivitis is 135 per 10,000 people.¹
- Viral conjunctivitis is more common than bacterial conjunctivitis.
- Allergic conjunctivitis had a point prevalence of 6.4% and a lifetime prevalence of 40% in a large population study in the United States from 1988 to 1994.²

ETIOLOGY AND PATHOPHYSIOLOGY

Conjunctivitis is predominately infectious (bacterial or viral) or allergic, and the most common etiologies vary by age.

- Neonatal conjunctivitis is often caused by *Chlamydia trachomatis* and *Neisseria gonorrhoeae*.³
- Children younger than 6 years are more likely to have a bacterial than viral conjunctivitis (**Figure 16-2**). In the United States, the

FIGURE 16-1 Viral conjunctivitis demonstrating bilateral conjunctival injection with little discharge. The patient has an incidental left eye conjunctival nevus. (Courtesy of Richard P. Usatine, MD.)

FIGURE 16-2 Unilateral conjunctivitis in a 4-year-old child. The child's age and purulent discharge are consistent with a bacterial etiology. (Courtesy of Richard P. Usatine, MD.)

most common bacterial causes are *Haemophilus* species and *Streptococcus pneumoniae* accounting for almost 90% of cases in children.⁴

- Children age 6 years or older are more likely to have viral or allergic causes for conjunctivitis.⁴ Adenovirus is the most common viral cause.

DIAGNOSIS

- To distinguish conjunctivitis from other causes of a red eye, ask about pain and check for vision loss. Patients with a red eye and intense pain or vision loss that does not clear with blinking are unlikely to have conjunctivitis and should undergo further evaluation.
- Always ask about contact lens use as this can be a risk factor for all types of conjunctivitis, including bacterial conjunctivitis (**Figure 16-3**).
- Typical clinical features of any type of conjunctivitis may include eye discharge, gritty or uncomfortable feeling, one or both pink eyes, and no vision loss. The infection usually starts in one eye, and progresses to involve the other eye days later.
- Bacterial conjunctivitis (see **Figures 16-2 to 16-4**) has a more purulent discharge than viral or allergic conjunctivitis.
- A clinical scoring system has been developed to distinguish bacterial from other causes of conjunctivitis in healthy adults who did not wear contact lenses. A score of +5 to -3 is determined as follows:
 - Two glued eyes (+5); one glued eye (+2); history of conjunctivitis (-2); eye itching (-1).
 - A score of +5, +4, or +3 is useful in ruling in bacterial conjunctivitis with specificities of 100%, 94%, and 92%, respectively.
 - Scores of -1, -2, or -3 are useful in ruling out bacterial conjunctivitis with sensitivities of 98%, 98%, and 100%, respectively.⁵

Allergic conjunctivitis is typically bilateral and accompanied by eye itching. Giant papillary conjunctivitis is a type of allergic reaction, most commonly to soft contact lenses (**Figure 16-5**).

LABORATORY TESTING

- An in-office rapid test for adenoviral conjunctivitis (RPS Adeno Detector) has a sensitivity of 88% and a specificity of 91% compared to viral cell culture with confirmatory immunofluorescence staining.⁶

DIFFERENTIAL DIAGNOSIS

- Episcleritis—Segmental or diffuse inflammation of episclera (pink color), mild or no discomfort but can be tender to palpation, and no vision disturbance (see also Chapter 17, Episcleritis and Scleritis).
- Scleritis—Segmental or diffuse inflammation of sclera (dark red, purple, or blue color), severe boring eye pain often radiating to head and neck, and photophobia and vision loss (see also Chapter 17, Episcleritis and Scleritis).
- Uveitis or iritis—360-degree perilimbal injection, eye pain, photophobia, and vision loss. Frequently treated initially as conjunctivitis without resolution (see also Chapter 18, Uveitis and Iritis).

FIGURE 16-3 Bacterial conjunctivitis with a small amount of discharge. The patient was unable to clean her contacts while being evacuated from a hurricane-threatened Houston and the conjunctivitis was bilateral. (Courtesy of Richard P. Usatine, MD.)

FIGURE 16-4 Gonococcus conjunctivitis has a copious discharge. This severe case resulted in partial blindness. (Courtesy of Centers for Disease Control and Prevention [CDC].)

- Keratitis or corneal ulcerations—Diffuse conjunctival injection, often with miosis (constriction of pupil), eye discharge, pain, photophobia, and vision loss depending on the location of ulceration. Herpes keratitis is a diagnosis that should not be missed (**Figures 16-6 and 16-7**). The use of fluorescein and a UV light can help identify dendritic ulcers or other corneal damage and prompt an emergent referral to an ophthalmologist (**Figure 16-7**). Contact lens wearers should urgently see an ophthalmologist for keratitis.
- Acute-angle closure glaucoma—Cloudy cornea and scleral injection, eye pain with ipsilateral headache, elevated intraocular pressure, and severe vision loss (see also Chapter 19, Glaucoma).
- A foreign body in the eye can cause conjunctival injection and lead to a bacterial superinfection. If the foreign body is not easily dislodged with conservative measures, or appears to be superinfected with ulceration or leukocyte infiltrate, prompt referral to an ophthalmologist is required (**Figure 16-8**).

Trachoma is an eye infection caused by *C. trachomatis* that is rare in the United States but common in the rural areas of some developing countries. It is a leading cause of blindness in the developing world. Poverty and poor hygiene are major risk factors. Once the eye is infected, follicles can be seen on the upper tarsal conjunctiva upon eyelid eversion (**Figure 16-9**). Superior tarsal conjunctival scarring leads to entropion, which causes corneal scarring and ultimately blindness (**Figure 16-10**).

Vernal conjunctivitis is a severe recurrent form of allergic conjunctivitis that is more common in the summer (not the spring). The term *vernal* refers to the spring time, and therefore it is now referred to as “warm weather conjunctivitis” rather than “spring catarrh.” Giant papillae that look like a cobblestone pattern may be seen in this condition. It occurs primarily in young boys, and typically ceases to recur seasonally with age.

MANAGEMENT

Hand hygiene can control the spread of infectious conjunctivitis.

Most acute conjunctival infections are viral and resolve without treatment. Following are the categories of patients who have a high probability of bacterial conjunctivitis and who are treated with topical antibiotics:

- Children younger than age 6 years.⁴
 - Azithromycin 1.5% ophthalmic solution twice daily for 3 days resulted in a clinical and microbiologic cure in more than 80% of children. This dosing regimen provides equivalent efficacy to 4 times a day dosing of tobramycin.^{7,8}
- Adults who score +3 or above on the clinical scoring system for bacterial conjunctivitis.
- Studies show that more than 80% of patients show improvements with 0.3% ciprofloxacin, tobramycin, norfloxacin, or gentamicin.^{9,10}
- Levofloxacin 0.5% is dosed 3 times a day.¹¹
- Delayed antibiotic prescription decreased antibiotic use by nearly 50% and provided similar symptom control compared to immediate antibiotics.¹²

Allergic conjunctivitis can be treated with antihistamines, mast-cell stabilizers, nonsteroidal antiinflammatory agents, corticosteroids, and immunomodulatory agents.¹³

FIGURE 16-6 Herpetic keratitis in a 56-year-old woman staying in a shelter after Hurricane Katrina. (Courtesy of Richard P. Usatine, MD.)

FIGURE 16-7 Slit-lamp view of a dendritic ulcer with fluorescein uptake from herpetic keratitis. (Courtesy of Paul D. Comeau.)

REFERRAL

- Refer patients who have vision loss, copious purulent discharge (this could represent gonococcal disease, which must be cultured, and which can cause vision loss), severe pain, lack of response to therapy, or a history of herpes simplex or zoster eye disease to an ophthalmologist.
- Any patient who may need ocular steroid should be seen by an ophthalmologist. There is a severe risk for complications with the use of ocular steroids.

PREVENTION

Good hygiene practices with washing of the hands and face with soap and water.

FOLLOW-UP/RETURN TO SCHOOL

Routine follow-up is generally not needed if symptoms resolve in 3 to 5 days.

State health departments have no consensus on when children with conjunctivitis can return to school. A literature-based review suggests the best strategy is excluding children from school until they are asymptomatic.¹⁴

PATIENT EDUCATION

- Most adults and children older than age 6 years have a nonbacterial cause of conjunctivitis.
- Remove contact lenses until conjunctivitis has resolved.
- Avoid touching the face or rubbing the eyes and wash hands immediately afterwards.
- Do not share face towels, eye make-up, or contact lens cases.
- Inform your physician immediately if you experience eye pain or vision loss.

17 SCLERITIS AND EPISCLERITIS

Heidi Chumley, MD
Kelly Green, MD

PATIENT STORY

A 45-year-old woman presents with 1 day of increasing eye pain, eye redness, and difficulty in seeing. On examination there was scleral injection and exquisite globe tenderness (**Figure 17-1**). Her review of systems is positive for morning stiffness and swelling in both of her hands. The patient was urgently referred to an ophthalmologist who diagnosed her with scleritis. Her visual acuity was reduced minimally. A slit lamp exam revealed injected sclera with a bluish hue in the affected eye and a rare anterior chamber cell. The posterior segment was normal.

The ophthalmologist prescribed an oral NSAID, specifically indomethacin, as it effectively crosses the blood-brain barrier and gets good levels in the eye.

Her rheumatoid factor was positive, so she was also referred to a rheumatologist.

INTRODUCTION

Episcleritis and scleritis are inflammation of the deeper layers of the eye, the vascular episclera, and the avascular sclera. Episcleritis presents with segmental eye redness, discomfort but not severe pain, and no vision loss. Scleritis can have overlying episcleritis, but also has a violaceous hue, is painful, and may cause vision loss. Scleritis typically has an associated underlying condition (autoimmune or infectious) that should be identified and treated. Scleritis is treated with NSAIDs, systemic glucocorticoids, or immunosuppressive medications. Patients with scleritis are often referred to an ophthalmologist as vision loss is common.

EPIDEMIOLOGY

Scleritis

- Scleritis usually presents between the ages of 30 and 50 years and is twice as common in women compared to men.¹
- Forty-four percent of patients presenting with scleritis to specialty health centers were found to have an associated systemic disease (37% rheumatic, 7% infection), most commonly (15%) rheumatoid arthritis.²

Episcleritis

- Prevalence is unknown.
- Usually presents between the ages of 20 and 50 years and may be more common in women.
- Nodular or recurrent episcleritis is more likely to be associated with an underlying systemic condition than is an isolated episode of simple episcleritis.

FIGURE 17-1 Scleritis in a patient with eye pain and exquisite globe tenderness. Untreated this can result in loss of vision. (Courtesy of Paul D. Comeau.)

ETIOLOGY AND PATHOPHYSIOLOGY

- Scleritis and episcleritis are inflammatory conditions causing congestion of the deeper 2 of the 3 vascular layers (conjunctival, episcleral, and scleral plexuses) overlying the avascular sclera.
- Scleritis often occurs with episcleritis; episcleritis does not involve the sclera and does not progress to scleritis.
- Scleritis disrupts vascular architecture and may cause vision loss; episcleritis does not.
- Causes of scleritis:
 - Systemic autoimmune diseases such as rheumatoid arthritis, Wegener granulomatosis, seronegative spondyloarthropathies, relapsing polychondritis, systemic lupus erythematosus (SLE). **Figure 17-2** shows a young woman with SLE and scleritis.
 - Infections (*Pseudomonas*, tuberculosis, syphilis, herpes zoster).
 - Less common causes include gout and sarcoidosis.
 - Idiopathic.
- Causes of episcleritis
 - Most often idiopathic.
 - May be associated with any of the conditions listed above, especially if the presentation is nodular or recurrent.

DIAGNOSIS

CLINICAL FEATURES

Scleritis

- Segmental or diffuse inflammation of sclera (dark red, purple, or blue color), with overlying episclera and conjunctival inflammation (**Figures 17-1 to 17-3**).
- Severe, boring eye pain often radiating to head and neck that worsens with eye movement. However, 20% of patients may not have pain, including those with the necrotizing type (scleromalacia perforans) and those taking immunosuppressive agents prior to the onset of scleritis.¹
- Photophobia and vision loss.

Episcleritis

- Segmental or diffuse inflammation of episclera (pink color) and overlying conjunctival vessel injection (**Figures 17-4 and 17-5**).
- Mild if any discomfort but can be tender to palpation.
- No vision disturbance.
- Scleritis and episcleritis are often distinguished by history and physical examination features; however, when scleritis has extensive overlying episcleritis, the diagnosis becomes more difficult. Scleritis must be differentiated from episcleritis because scleritis requires treatment and an evaluation for underlying medical conditions.
- Ten percent phenylephrine blanches inflamed episcleral and conjunctival vessels, but not scleral vessels; in scleritis, this can reveal a focus of scleral engorgement covered by episcleral injection.
- Scleritis and episcleritis, as opposed to iritis with overlying episcleral injection, often have areas of focal tenderness to palpation. These can be elicited with a sterile cotton swab after applying a topical anesthetic.

FIGURE 17-2 Scleritis in a young woman with systemic lupus erythematosus. Note the malar rash that is also present. (Courtesy of Richard P. Usatine, MD.)

FIGURE 17-3 Scleritis in a patient with Wegener granulomatosis. Deep vessels are affected, giving the eye a purplish or blue hue. (Courtesy of Everett Allen, MD.)

Typical distribution

- Scleritis can be posterior (posterior to the medial and lateral rectus muscles) or anterior:
 - Posterior scleritis can produce retinal detachments and subretinal exudates and is often associated with uveitis (inflammation of the iris, ciliary body, or choroid).
 - Anterior scleritis can be diffuse, nodular, necrotizing with inflammation or necrotizing without inflammation.¹
- Scleritis is bilateral in 50% of patients.¹
- Episcleritis is often segmental, but can be diffuse, and is typically benign.

LABORATORY TESTING

In scleritis, if an associated systemic disease has not been previously diagnosed, consider ordering these tests: complete blood count, metabolic panel, urinalysis, antineutrophil cytoplasmic antibody, antinuclear antibody, rheumatoid factor, anticyclic citrullinated peptide antibodies, rapid plasma reagin, and Lyme antibody in Lyme infested regions. Also consider tuberculin skin test, viral hepatitis panel, and cultures for bacteria, virus, and fungi.

IMAGING

In scleritis, if an associated systemic disease has not been previously diagnosed, consider the following: chest radiographs, sinus CT, or sacroiliac joint radiographs.

To diagnose posterior scleritis, ultrasound or orbital CT can demonstrate sclera thickening.

BIOPSY

An ophthalmologist may perform a biopsy when it is important to distinguish among scleritis caused by rheumatic diseases, infections, or sarcoidosis.

- Rheumatic—Zonal necrotizing granulomatous scleral inflammation with loss of anterior scleral tissue.
- Infectious—Necrotizing scleritis with microabscesses.
- Sarcoid—Sarcoidal granulomatous inflammation can be identified in cases of sarcoidosis.

DIFFERENTIAL DIAGNOSIS

Causes of red eye, other than scleritis and episcleritis:

- Uveitis or iritis—360 degrees perilimbal injection, which is most intense at the limbus; eye pain, photophobia, and vision loss (see also Chapter 18, Uveitis and Iritis).
- Keratitis or corneal ulcerations—Diffuse erythema with ciliary injection often with pupillary constriction; eye discharge; pain, photophobia, and vision loss depending on location of ulceration.
- Conjunctivitis—Conjunctival injection, eye discharge, gritty or uncomfortable feeling, no vision loss (see Chapter 16, Conjunctivitis).
- Acute-angle closure glaucoma—Cloudy cornea and scleral injection; eye pain with ipsilateral headache; severe vision loss (see Chapter 19, Glaucoma).

FIGURE 17-4 Episcleritis showing inflammation of the conjunctival and episcleral tissue with associated vascular engorgement. A sector of this eye is involved and that is typical. Vessels were blanched with 2.5% phenylephrine, which helped distinguish this from scleritis. (Courtesy of Paul D. Comeau.)

FIGURE 17-5 Episcleritis showing inflammation of only the conjunctival and episcleral tissue. Note the absence of violaceous color that is seen in scleritis. (Courtesy of Richard P. Usatine, MD.)

MANAGEMENT

For patients presenting with scleritis who do not have a previously diagnosed associated systemic condition, a search for an underlying cause is indicated.

- Evaluate for signs and symptoms of rheumatoid arthritis, Wegener's granulomatosis (respiratory or renal symptoms), relapsing polychondritis (vasculitis around ear or nose cartilage or trachea), and seronegative spondyloarthropathies (inflammatory back pain, arthritis, and inflammatory bowel symptoms).
- Evaluate for signs, symptoms, and risk factors for infection including eye trauma, recent ocular surgery, recurrent herpes simplex or varicella zoster, or risk factors for tuberculosis.
- Evaluate for signs and symptoms of gout and sarcoidosis.

MEDICATIONS

- Scleritis is initially treated with systemic NSAIDs and/or topical steroids; however, in one study only 47% of patients responded to 2 drops of 1% prednisolone every 2 hours for up to 2 weeks.³ **SOR B**
- Scleritis that does not respond to NSAIDs and/or topical steroids; may need systemic steroids, subconjunctival steroids, or immune modulators. **SOR C**
- Episcleritis often resolves spontaneously. Eye redness and irritation improve by 50% in less than a week. Treatment with topical NSAIDs was no better than artificial tears on measures of redness and comfort.⁴ **SOR B**

REFERRAL

- If you suspect scleritis, refer the patient to an ophthalmologist immediately. This is especially important if there is any visual loss or eye pain.
- If episcleritis is not resolved, refer to an ophthalmologist.

PROGNOSIS

Simple episcleritis improves in 7 to 10 days. Episcleritis that is nodular or associated with an underlying disease may take 2 to 3 weeks to resolve.

Patients who smoke may take longer to recover from episcleritis or scleritis. One retrospective trial demonstrated that patients who smoked and had episcleritis or scleritis were 5.4 times more likely to have a delayed response of more than 4 weeks to any medication (95% CI = 1.9 to 15.5).⁵

Vision loss with scleritis is common and the risk is dependent on the type of scleritis: diffuse anterior, 9%; nodular, 26%; necrotizing, 74%; posterior, 84%.⁶

FOLLOW-UP

- Advise patients with episcleritis to return for any increases in eye pain, changes in vision, or no improvement in 1 week.
- Advise patients with scleritis to follow-up testing for underlying systemic illnesses. If none is found, consider retesting as patients with idiopathic scleritis develop a systemic illness at a 4% annual rate.²

PATIENT EDUCATION

- Reassure patients with episcleritis of its generally benign nature and that oral NSAIDs may be used for discomfort.
- Advise patients with scleritis of its association with systemic illnesses and the need for further work-up.

18 UVEITIS AND IRITIS

Heidi Chumley, MD

PATIENT STORY

A 28-year-old man presented with sudden onset of a right red eye, severe eye pain, tearing, photophobia, and decreased vision. He denied eye trauma. His review of systems was positive for lower back pain and stiffness over the past year. On examination, he had a ciliary flush (**Figure 18-1**) and decreased vision. He was referred to an ophthalmologist who confirmed the diagnosis of acute anterior uveitis. He was found to be HLA-B27 positive with characteristics of ankylosing spondylitis. His uveitis was treated with topical steroids.

INTRODUCTION

Uveitis is inflammation of any component of the uveal tract: iris (anterior), ciliary body (intermediate), or choroid (posterior). Most uveitis is anterior and is also called iritis. Uveitis is caused by trauma, inflammation, or infection and the most common etiologies vary by location in the uveal tract. Patients present with vision changes and, if uveitis is anterior, eye pain, redness, tearing, and photophobia. All patients with uveitis should be referred to an ophthalmologist.

SYNONYMS

Anterior uveitis includes iritis and iridocyclitis. *Iritis* is when the inflammation is limited to the iris. If the ciliary body is involved too, then it is called *iridocyclitis*. Posterior uveitis includes choroiditis and chorioretinitis.

EPIDEMIOLOGY

- Annual incidence of uveitis is 17 to 52 per 100,000 population and prevalence is 38 to 714 per 100,000 population.¹
- Occurs at any age, but most commonly between 20 and 59 years.¹
- Anterior uveitis (iritis) accounts for approximately 90% of uveitis as seen in primary care settings.¹
- Eighty percent of uveitis cases seen in children are caused by juvenile rheumatoid arthritis.²
- In the United States, noninfectious uveitis accounts for 10% of legal blindness.³

ETIOLOGY AND PATHOPHYSIOLOGY

- Uveitis can be caused by trauma, infections, inflammation, or, rarely, neoplasms. Most likely causes differ by location.⁴
- Iritis—Trauma is common (**Figure 18-2**). In nontraumatic cases, causes include idiopathic (50%); seronegative spondyloarthropathies, that is, ankylosing spondylitis, reactive arthritis, psoriatic

FIGURE 18-1 Acute anterior uveitis with corneal endothelial white cell aggregates (*black arrow*) and posterior synechiae formation (iris adhesions to the lens, *white arrows*). (Courtesy of Paul D. Comeau.)

FIGURE 18-2 A young man with traumatic iritis (anterior uveitis) after being hit in the eye with a baseball. He has photophobia and eye pain. (Courtesy of Richard P. Usatine, MD.)

arthritis, inflammatory bowel disease (20%); and juvenile idiopathic arthritis (10%). Infections are less common and include herpes, syphilis, and tuberculosis.⁴

- Intermediate—Most are idiopathic⁴ (**Figure 18-3**).
- Posterior—Toxoplasmosis is the most common, followed by idiopathic.⁴
- Panuveitis (affecting all layers)—Idiopathic (22% to 45%) and sarcoidosis (14% to 28%).⁴ Unilateral panuveitis is often endophthalmitis (endogenous or related to trauma or surgery). Bilateral panuveitis can be caused by sarcoidosis or syphilis.

RISK FACTORS

Patients with Behçet disease and ankylosing spondylitis have uveitis more commonly than the general population (relative risk of 4 to 20) because of human leukocyte antigen (HLA) associations.⁵

DIAGNOSIS

CLINICAL FEATURES

Anterior acute uveitis presents with:

- Usually unilateral eye pain, redness, tearing, photophobia, and decreased vision.
- 360-Degree perilimbal injection, which is most intense at the limbus (see **Figures 18-1, 18-2, and 18-4**).
- History of eye trauma, an associated systemic disease, or risk factors for infection.
- Severe anterior uveitis may cause a hypopyon from layering of leukocytes and fibrous debris in the anterior chamber (**Figure 18-4**). Behçet syndrome and HLA-B27 disease are the only two common noninfectious causes of hypopyon.

Intermediate and posterior uveitis:

- Presents with altered vision or floaters.
- Often there is no pain, redness, tearing, or photophobia.

Sarcoid uveitis presents with:

- Panuveitis (anterior, intermediate, and posterior).
- Gradual and usually a bilateral onset.
- Few vision complaints unless cataracts or glaucoma develops.
- Characteristic findings on slit-lamp examination (i.e., mutton-fat keratic precipitates, posterior iris synechiae).⁶

Typical distribution

- Anterior uveitis is typically unilateral and sarcoid uveitis is typically bilateral.

DIFFERENTIAL DIAGNOSIS

Causes of red eye, other than uveitis:

- Scleritis—Segmental or diffuse inflammation of sclera (dark red, purple, or blue color); severe, boring eye pain often radiating to

FIGURE 18-3 Idiopathic intermediate uveitis. The ciliary flush is perilimbal injection from dilation of blood vessels adjacent to the cornea, extending 3 mm into the sclera. Perilimbal injection may appear as a violet hue around the limbus with blurring of individual vessels. (Courtesy of Paul D. Comeau.)

FIGURE 18-4 Hypopyon with severe anterior uveitis, showing layering of leukocytes and fibrinous debris in the anterior chamber. May be sterile or infectious. An intense ciliary flush is seen. Most commonly seen in HLA-B27-positive patients with uveitis. Hypopyon may also be a presenting sign of malignancy (retinoblastoma and lymphoma). (Courtesy of Paul D. Comeau.)

head and neck; and photophobia and vision loss (see Chapter 17, Scleritis and Episcleritis).

- Episcleritis—Segmental or diffuse inflammation of episclera (pink color), mild or no discomfort but can be tender to palpation, and no vision disturbance (see Chapter 17, Scleritis and Episcleritis).
- Keratitis or corneal ulcerations—Diffuse erythema with ciliary injection often with constricted pupil; eye discharge; and pain, photophobia, and vision loss depending on the location of ulceration. Frequently associated with trauma, a history of herpes simplex virus (HSV) infection, or contact lens wear. Needs urgent evaluation by an ophthalmologist. There will be staining of the cornea with fluorescein.
- Conjunctivitis—Conjunctival injection, eye discharge, gritty or uncomfortable feeling, and no vision loss (see Chapter 16, Conjunctivitis). Recent history of red eye contacts or URI symptoms.
- Acute-angle closure glaucoma—Cloudy cornea and scleral injection, eye pain with ipsilateral headache, and severe vision loss (see Chapter 19, Glaucoma). May be a family history of same.

MANAGEMENT

Refer patients for any red eye along with loss of vision to an ophthalmologist. Patients with uveitis warrant additional examinations by the ophthalmologist.

- Traumatic uveitis—Dilated funduscopy for other ocular trauma, measurement of intraocular pressure, gonioscopy to evaluate for angle recession and risk for future glaucoma, and treatment may include steroid and/or cycloplegics for comfort.
- Nontraumatic uveitis—Slit-lamp examination and laboratory tests to assist with diagnosis of underlying cause; treatment is based on underlying cause but is usually topical steroid drops with or without cycloplegia.
- Therapeutic dilation is used to break the posterior synechiae that can occur (**Figure 18-5**).

PROGNOSIS

Uveitis causes vision loss, cataract, and often glaucoma if treatment is delayed or not provided. HLA-B27 disease is the most common etiology for anterior uveitis, and is associated with recurrent, bilateral anterior uveitis.

FOLLOW-UP

Appropriate follow-up is based on the underlying cause.

PATIENT EDUCATION

- See a physician immediately for a red eye with loss of vision.
- A series of tests may be performed to determine the cause of the uveitis; however, the underlying cause is often elusive.

FIGURE 18-5 This patient with uveitis had posterior synechiae that are attachments of the iris to the anterior capsule of the lens. Therapeutic dilation broke the synechiae, but left residual pigment on the anterior capsule. (Courtesy of Paul D. Comeau.)

19 GLAUCOMA

Heidi Chumley, MD

PATIENT STORY

A 50-year-old black man was noted to have a large cup-to-disc ratio during a funduscopy examination by his primary care provider (**Figure 19-1**). The patient reported no visual complaints. Further evaluation revealed elevated intraocular pressure and early visual field defects. He was started on medication to lower his intraocular pressure. He remained asymptomatic, and his visual field defects did not progress for the next several years.

INTRODUCTION

Glaucoma is a leading cause of blindness in the United States and globally. Open-angle glaucoma is an acquired loss of retinal ganglion cells characterized by either normal or increased intraocular pressure, a large cup-to-disc ratio, and visual field defects. Open-angle glaucoma is treated by reducing intraocular pressure, most commonly with eye drops. Angle-closure glaucoma, which is much less common, is an acute increase in intraocular pressure from a mechanical obstruction that must be treated emergently to preserve vision.

EPIDEMIOLOGY

- Approximately 2.5 million persons in the United States have glaucoma.
- Glaucoma is the second leading cause of blindness in the United States and the leading cause of blindness among African Americans.¹
- Population studies predict there will be 60.5 million people worldwide with glaucoma by 2010, and of these, 74% will have open-angle glaucoma.²
- Women comprise approximately 60% of all glaucoma cases, but 70% of patients with acute angle-closure glaucoma.²
- Asians comprise approximately 47% of all glaucoma cases, but 87% of acute angle-closure glaucoma.²
- The incidence of primary open-angle glaucoma was 8.3 per 100,000 population in people older than 40 years in a Minnesota population study.³
- According to a population-based study, a family history of glaucoma increased the risk of having glaucoma (odds ratio [OR] = 3.08).⁴

ETIOLOGY AND PATHOPHYSIOLOGY

- Glaucoma pathophysiology is incompletely understood, but the end point is the acquired loss of retinal ganglion cells and axons with resulting irreversible vision loss.

FIGURE 19-1 A 50-year-old man with glaucoma has an increased optic cup-to-disc ratio of 0.8. Median cup-to-disc ratio is 0.2 to 0.3, but varies considerably among individuals. (Courtesy of Paul D. Comeau.)

- Increased intraocular pressure (IOP) is a well known risk factor; however, recent attention has turned to ocular perfusion pressure (OPP), the difference between blood pressure (BP) and IOP. OPP is essentially BP minus IOP. As such, OPP is decreased by either high IOP or low BP.⁵ If a patient with apparently well-controlled IOP continues to have progressive visual field loss, it may be because of lack of perfusion of the optic nerve from aggressively lowered diastolic BPs. Therefore the management of glaucoma requires attention to diastolic BP.
- Glaucoma is categorized as either:
 - Open-angle—Dysfunction of the aqueous humor drainage system with no visible pathology to the anterior chamber angle.
 - Angle-closure—Occlusion of the anterior chamber angle.
- Impaired outflow of aqueous humor elevates IOP in some patients, but many patients with open-angle glaucoma have normal IOPs.
- Optic nerve atrophy is seen as optic disc cupping and irreversible visual field loss. Compare **Figures 19-1** and **19-2** to see the difference between abnormal (**Figure 19-1**) and normal (**Figure 19-2**) optic disc cupping.

RISK FACTORS

Open-angle risk factors include:

- Nonmodifiable: age older than 50 years, first-degree family history, and African ancestry.⁶
- Modifiable: high IOP, high or low BP, and maybe diabetes mellitus.⁶

Acute closed-angle glaucoma is more common in persons of Asian descent.

DIAGNOSIS

CLINICAL FEATURES

- Open-angle glaucoma:
 - History—Usually asymptomatic, occasionally “tunnel vision.”
 - Physical examination—Optic cupping and/or elevated IOP (glaucomatous changes can occur with IOPs in the normal range), loss of peripheral vision by automated perimetry (typically bilateral, but may be asymmetric).
- Acute closed-angle glaucoma:
 - History—Painful red eye (unilateral), vision loss, headache, nausea, halos around lights, and vomiting (**Figure 19-3**).
 - Physical examination—Shallow anterior chamber, optic cupping and elevated IOP, injection of the conjunctiva, and cloudy cornea (**Figure 19-3**).
- Typical distribution
 - Open-angle glaucoma is typically bilateral.
 - Closed-angle glaucoma is typically unilateral. However, there is risk for the other eye to undergo the same process, as the abnormal anatomically narrow angle is usually present in the other eye too.

FIGURE 19-2 Normal eye with a normal cup-to-disc ratio of 0.4. A cup-to-disc ratio of more than 0.5 requires further evaluation. (Courtesy of Paul D. Comeau.)

FIGURE 19-3 Acute closed-angle glaucoma with a painful red eye, vision loss, headache, nausea, and vomiting. This is a phacomorphic (i.e., lens induced) secondary acute angle closure. The mature cataract increased in anteroposterior (AP) diameter thus moving the lens-iris diaphragm forward and closing off the angle as well as the pupil thus resulting in high intraocular pressure, injected conjunctiva, and a cloudy cornea. (Used with permission from *The American Academy of Ophthalmology*.)

PROGNOSIS

Most patients with open-angle glaucoma, provided they are treated, will not lose vision.

Angle-closure glaucoma must be treated emergently to prevent vision loss.

FOLLOW-UP

Patients with glaucoma should have regular measurements of their IOP and visual fields to follow treatment efficacy.

PATIENT EDUCATION

Advise patients that glaucoma is a progressive disease requiring continued therapy to prevent vision loss.

20 DIABETIC RETINOPATHY

Heidi Chumley, MD
Kelly Green, MD

PATIENT STORY

A 38-year-old man saw a physician for the first time in 10 years after noticing visual loss in his left eye. His history revealed many risk factors for and symptoms of diabetes mellitus (DM). On an undilated fundoscopic examination, his physician was able to see some hemorrhages and hard exudates. A fingerstick in the office showed a blood glucose level of 420 mg/dL. He was treated for DM and referred to an ophthalmologist to be evaluated for his diabetic retinopathy (**Figure 20-1**).

INTRODUCTION

Diabetic retinopathy (DR) is a leading cause of blindness in the United States. Nonproliferative DR is characterized by microaneurysms, macular edema, cotton-wool spots, superficial (flame) or deep (dot-blot) hemorrhages, and exudates. Proliferative DR also has neovascularization of the retina, optic nerve head, or iris. Because patients may be asymptomatic until vision loss occurs, screening is indicated in all diabetic patients. Excellent glycemic control lowers a patient's risk of developing DR.

EPIDEMIOLOGY

- In developed nations, DR is the leading cause of blindness among people younger than age 40 years.¹
- In a community-based study, 29% of adults older than age 40 years with DM had DR. Prevalence in black patients was higher than in white patients (38.8% vs. 26.4%).²
- Twenty-one percent of patients have retinopathy at the time type 2 diabetes is diagnosed.³
- More than 60% of patients with type 2 DM have retinopathy within 20 years of diagnosis.³
- After 40 years of type 1 DM, 84% of patients have retinopathy.⁴

ETIOLOGY AND PATHOPHYSIOLOGY

- Hyperglycemia results in microvascular complications including retinopathy.
- Several biochemical pathways linking hyperglycemia and retinopathy have been proposed.³
- In nonproliferative retinopathy, microaneurysms weaken vessel walls. Vessels then leak fluid, lipids, and blood resulting in macular edema, exudates, and hemorrhages (**Figures 20-1** and **20-2**).
- Cotton-wool spots result when small vessel occlusion causes focal ischemia to the superficial nerve fiber layer of the retina.

FIGURE 20-1 Dilated fundoscopic photograph demonstrating microaneurysms (small red swellings attached to vessels), which are often the first change in diabetic retinopathy. Also present are flame hemorrhages (*black oval*) hemorrhages and hard exudates (*yellow*). Some of the hard exudates are demonstrated with white arrowheads. This case is an example of diabetic nonproliferative retinopathy. (Courtesy of Paul D. Comeau.)

FIGURE 20-2 Very severe nonproliferative diabetic retinopathy with multiple deep dot-blot hemorrhages, venous beading, and looping. This patient may benefit from panretinal photocoagulation. (Courtesy of Paul D. Comeau.)

- In proliferative retinopathy, new blood vessels form in response to ischemia (**Figure 20-3**).

RISK FACTORS

- In type 1 DM, identified risk factors include: longer diabetes duration, high hemoglobin (Hgb) A_{1c}, hypertension, smoking, and male gender.^{4,5}
- In type 2 DM, identified risk factors include: longer diabetes duration, high HgbA_{1c}, elevated systolic blood pressure, male gender, presence of albuminuria, and pharmacologic therapy.⁶

DIAGNOSIS

Definitive diagnosis is made by an eye specialist:

- Gold standard is grading of stereoscopic color fundus photographs in seven standard fields.³
- In comparison with the gold standard, a single monochromatic digital photo through a nondilated eye is sufficient to determine the presence or absence of DR with a sensitivity and specificity of 71% and 96%, respectively.⁷ **SOR B**

CLINICAL FEATURES

- Central vision loss as a result of macular edema or macular ischemia.
- Nonproliferative retinopathy—Microaneurysms are seen initially (mild), followed by macular edema, cotton-wool spots, superficial (flame) or deep (dot-blot) hemorrhages, and exudates (**Figure 20-1** shows moderate, and **Figure 20-2** shows severe).
- Proliferative retinopathy—Neovascularization, that is, growth of new blood vessels on the optic disc (**Figure 20-3**), the retina, or iris.

DIFFERENTIAL DIAGNOSIS

Retinopathy is also seen with other systemic illnesses and infections including:

- Hypertensive retinopathy—Arterial narrowing or arteriovenular nicking in addition to cotton-wool spots (see Chapter 21, Hypertensive Retinopathy).
- HIV retinopathy—Cotton-wool spots and infections such as *Cytomegalovirus*.

MANAGEMENT

Control diabetes and vascular risk factors:

- Glycemic control lowers the risk of retinopathy (35% risk reduction per 1 point HgbA_{1c} reduction).³ **SOR A**
- Blood pressure control improves visual outcomes (34% risk reduction in retinopathy progression; 47% risk reduction for declines in visual acuity).³ **SOR A**

FIGURE 20-3 Proliferative diabetic retinopathy showing newly developed, porous, friable blood vessels. New vessels can be seen on the optic disc and peripheral retina. Panretinal photocoagulation may help prevent vitreous hemorrhage, retinal detachment, and neovascular glaucoma. (Courtesy of Paul D. Comeau.)

FIGURE 20-4 This vitreous hemorrhage occurred when friable neovascular membranes broke spontaneously. The patient described a “shower of red dots” obscuring the vision and then loss of vision in that eye. (Courtesy of Paul D. Comeau.)

- Treatment with angiotensin-converting enzyme inhibitors (ACEIs) or angiotensin receptor blockers (ARBs) in type 1 DM or an ARB in type 2 DM have been shown to reduce retinopathy progression independent of blood pressure control.^{8,9} **SOR B**
- Patients with high lipids have more hard exudates and a higher risk of vision loss, but it is unclear if lipid control changes outcomes. **SOR C**

REFERRAL

Work with an ophthalmologist to prevent vision loss:

- Complications of DR are vitreous hemorrhage (**Figure 20-4**), retinal detachment, and neovascular glaucoma. Each of these complications can result in devastating vision loss.
- Ophthalmologists will determine when peripheral retinal photocoagulation is indicated (**Figure 20-5**). Photocoagulation reduces the risk of severe visual loss by more than 50% with side effects of peripheral and night vision loss.¹⁴ **SOR A** Other surgical treatments, including vitrectomy, have been less successful.³

PREVENTION

Prevent DR by preventing development of type 2 DM or tightly controlling type 1 or type 2 DM.

Screen patients with DM for DR based on national recommendations:¹⁰

- Type 1 DM—Adults and children older than age 10 years: Screen for retinopathy 5 years after diagnosis and at regular intervals as recommended by an eye specialist.
- Type 2 DM—Screen for retinopathy at diagnosis and then annually.

Patients can be referred to an eye specialist, or screened using telemedicine or retinal photographs taken during outreach screenings or in primary care offices.^{11,12}

Mathematical models are being developed to individualize screening frequency. In one study, screening intervals ranged from 6 to 60 months (mean: 29 months). This resulted in 59% fewer visits than with fixed annual screening without compromising safety.¹³

FOLLOW-UP

Once DR is diagnosed, frequency of examination is set by the ophthalmologist.

PATIENT EDUCATION

Preventing retinopathy by controlling diabetes and hypertension leads to better vision outcomes than any available treatment.^{3,14}

PATIENT RESOURCES

- National Eye Institute—<http://www.nei.nih.gov/health/diabetic/>.

FIGURE 20-5 Panretinal photocoagulation is the application of laser burns to the peripheral retina. The ischemic peripheral retina is treated with thousands of laser spots to presumably eliminate vasogenic factors responsible for the development of neovascular vessels. Laser spots cause scarring of the retina and choroid. The scars may be hypotrophic (white spots) or hypertrophic (black spots). (Courtesy of Paul D. Comeau.)

21 HYPERTENSIVE RETINOPATHY

Heidi Chumley, MD
Kelly Green, MD

PATIENT STORY

A 37-year-old man comes in for a physical examination and is noted to have a blood pressure of 198/142 mm Hg. He has no symptoms at the time. The physician performs a dilated fundusoscopic examination and notes optic disc edema, cotton wool spots, flame hemorrhages, dot-blot hemorrhages, arteriovenous nicking, and exudates (**Figure 21-1**). Fortunately, the remainder of the neurological exam and the EKG are normal. The patient is sent to the emergency room to be evaluated further and treated for a hypertensive emergency.

INTRODUCTION

Hypertensive retinopathy (HR) develops from elevated blood pressure. HR is diagnosed clinically by the presence of classic retina findings seen on fundusoscopic examination or digital retinal photographs in a patient with hypertension. HR can result in vision loss. Treatment is control of blood pressure.

EPIDEMIOLOGY

- Prevalence of 7.7% (black) versus 4.1% (white) in a population study of men and women between 49 and 73 years of age without diabetes.¹
- Multiple studies show that patients with moderate HR are 2 to 3 times more likely to have a stroke than those without HR at the same level of blood pressure control independent of other risk factors.²

ETIOLOGY AND PATHOPHYSIOLOGY

High blood pressure results in these retinal findings:³

- Retinal vessels become narrow and straighten at diastolic blood pressure (DBP) of 90 to 110 mm Hg.
- Arteriovenous “nicking” (white oval in **Figure 21-1**) occurs when the arteriolar wall enlarges from arteriosclerosis, compressing the vein. Patients with hypertension are at risk for central and branch retinal vein occlusions, which can result in significant vision loss.
- Microaneurysms and flame hemorrhages (**Figures 21-1** and **21-2**) result from the increased intravascular pressure. Cotton-wool spots (dashed arrow in **Figure 21-2**) represent ischemia of the nerve fiber layer. Hard exudates indicate vascular leakage (*white arrowheads* in Chapter 20, **Figure 20-1**).
- DBP 110 to 115 mm Hg causes leakage of plasma proteins and blood products resulting in retinal hemorrhages and hard exudates (**Figures 21-1** to **21-4**).

FIGURE 21-1 Hypertensive retinopathy with optic disc edema, cotton wool spots, flame hemorrhages, dot-blot hemorrhages, arteriovenous nicking, and exudates. (Used with permission from EyeRounds.org and The University of Iowa.)

FIGURE 21-2 More advanced hypertensive retinopathy with flame hemorrhages (*white arrow*), arteriovenous nicking (*white oval*), and cotton-wool spots (*dashed arrow*). (Courtesy of Paul D. Comeau.)

- Optic nerve swelling occurs at DBP of 130 to 140 mm Hg (Figure 21-3).

DIAGNOSIS

The diagnosis is made clinically from typical retinal findings in a patient with hypertension. These findings can be seen using funduscopic examination or by viewing retinal digital images. Retinal digital images have a higher inter-observer reliability than funduscopic examination.⁴

CLINICAL FEATURES

In order of increasing severity:

- Mild arteriolar narrowing.
- Severe arteriolar narrowing plus arteriovenous nicking.
- Retinal hemorrhages, microaneurysms, hard exudation, cotton-wool spots.
- Swelling of the optic nerve head and macular star, also called accelerated or malignant HR.

TYPICAL DISTRIBUTION

- Bilateral and symmetrical

LABORATORY TESTING

- Laboratory tests are not needed to make the diagnosis.
- Recommended tests for patients with hypertension include urinalysis, blood glucose, hematocrit, serum potassium, creatinine, calcium, and a fasting lipid profile.
- 12-Lead ECG is also recommended.⁵

DIFFERENTIAL DIAGNOSIS

Retinal vessel narrowing, arteriovenous nicking, microaneurysms, retinal hemorrhages, hard exudates, and cotton-wool spots are also seen in other conditions that impair blood flow, including:

- Diabetic retinopathy (see Chapter 20, Diabetic Retinopathy).
- Radiation retinopathy.
- Venous or carotid artery occlusive disease.
- Systemic illnesses such as collagen vascular disease.
- Hematologic diseases such as anemia and leukemia.
- Systemic infectious diseases such as HIV.

Optic nerve swelling and a macular star (blurring of the macula in a star-like pattern) also occur in:

- Neuroretinitis.
- Diabetic papillopathy.
- Radiation optic retinopathy.
- Optic neuritis.
- Intracranial disease.

FIGURE 21-3 Malignant hypertensive retinopathy with optic nerve head edema (papilledema), flame hemorrhages (*white arrow*), cotton-wool spots (*black arrow*), and macular edema with exudates (*dashed arrows*). The patient was admitted to the hospital to treat malignant hypertension aggressively. (Courtesy of Paul D. Comeau.)

FIGURE 21-4 Branch retinal vein occlusion of a major retinal vein associated with hypertension. The patient noted new onset of blurred vision and visual field constriction. Flame hemorrhages are seen along the course of the obstructed vein. (Courtesy of Paul D. Comeau.)

MANAGEMENT

Patients with funduscopy findings of HR should have their blood pressure measured and treated to reduce the risk of heart and cerebrovascular disease.⁵ **SOR A**

- Nonpharmacologic:
 - Assist patients in smoking cessation. This will result in the greatest benefit in morbidity and mortality.
 - Reduce weight or maintain normal body mass index (BMI).
 - Eat a diet rich in fruits and vegetables and low in saturated fats.
 - Reduce sodium to less than 6 g of sodium chloride per day.
 - Engage in regular physical activity for 30 minutes most days of the week.
 - Limit alcohol to 2 drinks per day in men and 1 drink per day in women.
- Medications
 - Start a thiazide diuretic to achieve blood pressure of less than 140/90 mm Hg unless contraindicated; a blood pressure goal of 130/80 mm Hg should be used for patients with diabetes. Consider an angiotensin-converting enzyme inhibitor (ACEI) as an initial medication for patients with diabetes. Consider other medications only for patients with compelling indications.
 - Although the largest benefit in outcomes is seen with the first medication, additional medications should be considered to achieve blood pressure less than 140/90 mm Hg after weighing the risks and benefits with the patient.
 - Evaluate and manage other risk factors for cardiovascular disease, including high cholesterol and diabetes.

REFERRAL

Patients experiencing acute visual disturbances should be referred for evaluation of hemorrhage or optic nerve edema (**Figures 21-3** and **21-4**).

PREVENTION

- Maintain normal blood pressure through a healthy lifestyle and medications when needed.
- Patients with hypertension alone do not require routine funduscopy examination, unless they also have diabetes mellitus.⁶ **SOR A**
- Prevention is obtained by preventing and controlling high blood pressure.

PROGNOSIS

- Prognosis is associated with severity of hypertension retinopathy.
- Three-year survival in patients with mild arteriolar narrowing is 70% compared to 6% in patients with swelling of the optic nerve or macular star.⁷

FOLLOW-UP

Once diagnosed with hypertension, patients should be seen every month until blood pressure is controlled and then every 3 to 6 months.⁴ **SOR** **C**

PATIENT EDUCATION

- HR does not require treatment other than lowering blood pressure unless acute vision changes occur.
- Control of blood pressure typically reverses HR findings, except for optic nerve edema, which may result in permanent vision loss.
- Control of blood pressure also reduces the risk of heart attack and stroke.

22 PAPILLEDEMA

Heidi Chumley, MD

PATIENT STORY

A 29-year-old obese woman presented with chronic headaches that were worse in the morning or while lying down. She denied nausea or other neurologic symptoms. She had no other medical problems and took no medications. On examination, she had a visual acuity of 20/20 in both eyes, bilateral papilledema (**Figure 22-1**), no spontaneous venous pulsations (SVPs), and no other neurologic signs. She had a brain MRI showing no mass or hydrocephalus, and elevated intracranial pressure measured by lumbar puncture. She was diagnosed with idiopathic intracranial hypertension and was followed closely for any changes in her vision. She was started on acetazolamide and assisted with a weight-loss program. Her symptoms resolved over the course of 18 months.

INTRODUCTION

The term *papilledema* refers specifically to optic disc swelling related to increased intracranial pressure. When no localizing neurological signs or space-occupying lesion is present, idiopathic intracranial hypertension (IIH) is a likely cause in patients younger than age 45 years, especially obese women. Patients with IIH usually present with daily pulsatile headache with nausea and often have transient visual disturbances and/or pulsatile tinnitus. Patients often report a “whooshing” sound that they hear. Bilateral papilledema and visual field defects on a perimetry test are found in almost all patients. Elevated opening pressure on lumbar puncture is required for the diagnosis.

SYNONYMS

Pseudotumor cerebri or *benign intracranial hypertension*.

EPIDEMIOLOGY

IIH occurs in:

- 1 per 100,000 people.¹
- 20 per 100,000 obese females ages 15 to 44 years.¹
- Prevalence may be increasing with increasing obesity. A UK population study found a prevalence of 85.7 per 100,000 in obese women.²
- Mean age of diagnosis is approximately 30 years.

ETIOLOGY AND PATHOPHYSIOLOGY

The optic disc swells because of elevated intracranial pressure. In IIH, the cerebral spinal fluid pressure is increased. The cause of this

FIGURE 22-1 Papilledema from increased intracranial pressure. The optic disc is elevated and hyperemic with engorged retinal veins. The entire optic disc margin is blurred. Optic neuropathies can also have blurring of the entire disc margin, but often, only part of the disc is blurred. (Courtesy of Paul D. Comeau.)

increase in unknown, but a current hypothesis is that IIH is a syndrome of reduced cerebrospinal fluid (CSF) absorption.

RISK FACTORS

IIH is much more common in obese women of childbearing age.

DIAGNOSIS

Patients with papilledema should undergo imaging, preferably MRI, followed by lumbar puncture. IIH is a diagnosis of exclusion with the following criteria:³

- Signs and symptoms of increased intracranial pressure (headache, transient visual disturbances, papilledema).
- Normal neurologic examination, except a sixth nerve palsy may be present. This will lead to a complaint of diplopia.
- Elevated intracranial pressure is present, as measured by lumbar puncture opening pressure greater than 250 mm of water in the lateral decubitus position, with normal CSF on microscopic examination.
- No evidence of mass, hydrocephalus, or vascular lesions by MRI.
- No other identifiable cause of increased intracranial hypertension.

CLINICAL FEATURES

- More than 90% of patients with IIH are obese women of childbearing age. Look for a different diagnosis in children, men, and older patients.³
- Headaches and visual changes are the most common symptoms.
- Difficulty in thinking or concentrating is frequently reported. New studies indicate cognitive impairment, particularly in learning and memory.⁴
- SVP are retinal vein pulsations at the optic disc and are typically absent in IIH patients. SVP are seen in 90% of patients with normal intracranial pressure, and are absent when the CSF pressure is above 190 mm Hg. As the CSF pressure may be transiently normal in IIH, the presence of SVP does not preclude IIH, but indicates that the CSF pressure is normal at that moment.⁵

TYPICAL DISTRIBUTION

Papilledema is bilateral in the overwhelming majority of cases (see **Figures 22-1** and **22-2**). Unilateral optic disc swelling has been rarely noted with elevated intracranial pressure.

LABORATORY TESTING

Cerebral spinal fluid is typically sent for cell count and culture.

IMAGING

- Traditionally, imaging was used to rule out intracranial mass or venous sinus obstruction; however, several imaging modalities show promise as tools that may mitigate the need for recurrent lumbar punctures to monitor pressures.

FIGURE 22-2 Severe acute papilledema with papillary flame hemorrhages and cotton-wool spots that obscure the disc vessels. The blurred edges of the optic disc appear as a starburst. (Courtesy of Paul D. Comeau.)

- Transorbital sonography measurements of optic nerve sheath diameter detected raised intracranial pressure (ICP) with a sensitivity of 90% and a specificity of 84%.⁶
- Optical coherence tomography (OCT) is an imaging modality used in the ophthalmology office that can distinguish between a normal optic disc, moderate elevation, and papilledema in patients with IIH based on differences in retinal nerve fiber layer thickness.⁷
- MRI findings in IIH include optic nerve tortuosity, partial empty sella, and transverse sinus narrowing. These changes reverse after pressure is reduced and return if pressure increases.⁸

DIFFERENTIAL DIAGNOSIS

- Pseudopapilledema or optic disc drusen, an optic nerve anomaly that elevates the optic disc surface and blurs the disc margins, which can be caused by calcifications in the optic nerve head.
- Optic neuropathies, swelling of all or parts of one or both discs, which can be caused by ischemia or demyelination (as in multiple sclerosis), and may be seen in 1% to 2% of patients with diabetes mellitus type 1 or 2.⁹

Elevated intracranial pressure can also be caused by obstructing lesions, medical conditions, or medications:³

- Mass lesions, hydrocephalus, venous sinus or jugular venous thrombosis, and meningial infections.
- Addison disease, hypoparathyroidism, chronic obstructive pulmonary disease (COPD), sleep apnea, renal failure, pulmonary hypertension, and severe anemia.
- Antibiotics in the tetracycline family, vitamin A, anabolic steroids, lithium, and corticosteroid withdrawal.

MANAGEMENT

In many cases, IIH is self-limiting, presents without visual symptoms, and will resolve over several years without loss of vision. However, when patients present with persistent or worsening visual disturbances, treatment is required to lower the intracranial pressure to prevent optic nerve damage and irreversible loss of vision. Management of the headache is a key factor when choosing a therapeutic plan. Management includes the following:

- Nonpharmacologic
 - Careful observation (often by an ophthalmologist) with documentation of any visual changes. Formal visual field testing is indicated.
 - Weight loss of 15% of body weight is beneficial but will not decrease intracranial pressure quickly enough if visual compromise is present.¹ **SOR C**
- Medications
 - Acetazolamide 1000 to 2000 mg/day; early studies indicate that topiramate may also be effective; other diuretics such as furosemide are less effective.¹⁰ **SOR C**
 - High-dose corticosteroids for short time periods for rare cases of rapidly advancing vision loss.^{1,10} **SOR C**

- Refer or hospitalize
 - Surgical interventions for severe, recalcitrant cases include optic nerve sheath fenestration and lumbar peritoneal shunt. Surgery is also considered in special populations such as pregnant women and dialysis patients.^{1,10} **SOR** 
 - Transverse sinus stenting is a newer surgical technique that holds promise.¹¹

PREVENTION

Maintenance of ideal body weight may prevent IIH.

PROGNOSIS

Although approximately two-thirds of patients with IIH present with visual impairment, the majority of patients improve. One study reported 9% of patients had permanent visual loss.¹²

FOLLOW-UP

Patients should be followed every 3 to 6 months by a physician who can adequately view the entire optic disc and document visual acuity and visual field deficits. They should be seen immediately for any visual changes.

PATIENT EDUCATION

Advise patients with new papilledema of the need for an evaluation for dangerous causes of increased intracranial pressure, such as intracranial masses or underlying medical illnesses. Also advise patients that IIH often resolves spontaneously over several years, but they should report any visual changes immediately.

23 AGE-RELATED MACULAR DEGENERATION

Heidi Chumley, MD

PATIENT STORY

A 78-year-old white woman presents with loss of central vision that has gradually worsened over the last 6 months. Fully independent before, she can no longer drive and has difficulty with activities of daily living. Her peripheral vision remains normal. Funduscopy examination reveals macular depigmentation and drusen (yellowish-colored subretinal deposits on the macula) (**Figure 23-1**). She is diagnosed with dry, age-related macular degeneration. After her physician discusses the available information about antioxidants and therapeutic options, she decides to start antioxidants and see an ophthalmologist to discuss laser, surgical, or medical treatments.

INTRODUCTION

Age-related macular degeneration (AMD) causes central vision loss in elderly patients. The pathophysiology of AMD is incompletely understood, but involves chronic changes in the retina and retinal pigment epithelium mediated by environmental and genetic factors. AMD is diagnosed by ophthalmoscopic detection of drusen. Healthy lifestyle decreases the risk of development and progression of AMD. Refer patients to an ophthalmologist to evaluate for intravitreal injections, laser photocoagulation or photodynamic therapy, or surgery.

EPIDEMIOLOGY

AMD is the leading cause of irreversible vision loss in the industrialized world.

- Prevalence of advanced AMD is 1.4% in patients older than 40 years of age and 15% in white women older than 80 years of age.¹
- AMD that causes significant vision loss is more common in whites than blacks or Hispanics.²
- Smoking increases risk in women (relative risk [RR] 2.5 for current smokers; 2.0 for former smokers).²
- AMD aggregates in families, but the specific genetic and familial risk factors are not clear.²

ETIOLOGY AND PATHOPHYSIOLOGY

AMD affects central but not peripheral vision. Environment and genetic attributes increase risk of these pathologic changes with aging.³

- Oxidative stress from the buildup of free oxygen radicals causes retinal pigment epithelial (RPE) injury.

FIGURE 23-1 Intermediate, dry, age-related macular degeneration with macular depigmentation and drusen (yellowish-colored subretinal deposits on the macula). This patient has central vision distortion. (Courtesy of Paul D. Comeau.)

- RPE injury evokes a chronic inflammatory response. The complement system is involved and specific polymorphisms of complement genes are associated with advanced disease and progression.⁴
- RPE injury/inflammation forms an abnormal extracellular matrix (ECM), which alters diffusion of nutrients to the retina and RPE.
- The abnormal ECM and diffusion leads to retinal atrophy and new vessel growth.

RISK FACTORS

- For advanced AMD, strong risk factors are age, current cigarette smoking, previous cataract surgery (replaced lens provides less eye protection from sunlight), and family history of AMD.
- Moderate risk factors include higher body mass index, history of cardiovascular disease, hypertension, and high plasma fibrinogen.
- Weak or inconsistent risk factors include gender, ethnicity, diabetes, iris color, history of cerebrovascular disease, total cholesterol, high-density lipoprotein, and triglyceride levels.⁵

DIAGNOSIS

Diagnosis is made by ophthalmoscopy. AMD can be dry (early, intermediate, or advanced) or wet (always considered advanced).

- Early dry—May have no vision change; drusen present (**Figure 23-2**).
- Intermediate dry—Distortion in the center of vision; multiple medium-size drusen (see **Figure 23-1**).
- Advanced dry—(Nonexudative) Significant central vision loss from breakdown of support tissues around the macula.
- Advanced wet—(Exudative) Gradual or sudden significant loss of vision; new onset of distortion in vision (straight lines appear wavy); abnormal blood vessels grow under the macula and can cause hemorrhage (**Figure 23-3**). Late changes include subretinal scarring and retinal atrophy (**Figure 23-4**).

CLINICAL FEATURES

- Symptoms that occur before vision loss include metamorphopsia (distorted vision) and central scotoma (impaired vision at the point of fixation).⁶
- Vision loss is central. Peripheral and night vision are generally not affected.
- Drusen is the classic physical examination finding:
 - Hard: small, yellow punctuate nodules.
 - Soft: large pale yellow or grayish white with less distinct borders.

TYPICAL DISTRIBUTION

- Bilateral, although usually one eye is affected before the other.

ANCILLARY TESTING

Macular function is impaired before visual loss and can be detected by tests including: macular recovery function and central visual field

FIGURE 23-2 Early, dry, age-related macular degeneration demonstrating drusen, yellowish-colored subretinal deposits on the macula. Patients may have no visual complaints at this stage. (Courtesy of Paul D. Comeau.)

FIGURE 23-3 Late, wet, age-related macular degeneration (exudative) with subretinal hemorrhages. Patients usually have significant central vision loss. (Courtesy of Paul D. Comeau.)

sensitivity.⁷ Optical coherence tomography (OCT) and fluorescein angiography are most commonly used to assess for leakage from abnormal blood vessels. If leakage is present, this indicates that anti-vascular endothelial growth factor (VEGF) treatment may help.

DIFFERENTIAL DIAGNOSIS

Vision loss in the elderly can also be caused by any of the following:⁸

- Glaucoma (open-angle)—Often asymptomatic until late in the disease, but then has visual field defects instead of central vision loss; funduscopic examination may reveal a large cup-to-disc ratio (see Chapter 19, Glaucoma).
- Diabetic retinopathy—May have central vision loss with macular edema; funduscopic examination demonstrates microaneurysms, cotton-wool spots, hemorrhages, and exudates (see Chapter 20, Diabetic Retinopathy).
- Cataracts—Blurred vision or glare; lens opacities seen when examining the red reflex.

Drusen can also be seen with:

- Pigmented nevi and choroidal malignant melanoma.
- Retinal detachment.
- Glomerulonephritis, particularly membranoproliferative glomerulonephritis type II.⁶

MANAGEMENT

Refer to ophthalmologist to evaluate for treatments such as intravitreal injections, laser photocoagulation or photodynamic therapy, or surgery.

- Nonpharmacologic:
 - Healthy lifestyle that includes diet, exercise, and no smoking.
- Medications:
 - Intraocular injections of pegaptanib and ranibizumab (anti-VEGFs) reduce the risk of visual acuity loss in patients with advanced neovascular AMD, number needed to treat (NNT) 3–14.⁹ **SOR A**
 - Bevacizumab performs similarly to ranibizumab.¹⁰
 - Serious ocular/nonocular adverse events and mild ocular adverse events occur in 1% and 5% of injections, respectively.¹¹
- Complementary/alternative therapy:
 - Consider antioxidants (vitamin C, 500 mg; vitamin E, 400 IU; and beta-carotene, 15 mg) plus 80 mg zinc per day to decrease the risk of worsening vision loss in patients with intermediate to advanced AMD.¹² **SOR B** These antioxidants are available in single-tablet formulations. Avoid beta-carotene for smokers or people who have smoked in the last 10 years.

REFERRAL

- Most patients are treated by an ophthalmologist, and treatment may include intravitreal injections, laser photocoagulation or photodynamic therapy, or surgery.
- Urgently refer a patient with a history of dry AMD and acute changes in vision (distortion of lines, objects) to an ophthalmologist for evaluation and treatment.

FIGURE 23-4 Late, wet, age-related macular degeneration (exudative) with subretinal scarring. Patients usually have significant central vision loss resulting from destruction of tissue around the macula. (Courtesy of Paul D. Comeau.)

PREVENTION

- Healthy diet—People with healthy diets, compared with non-healthy diets, were 46% less likely to develop AMD.¹³
- Physical activity—Active people, compared to inactive people, were 54% less likely to develop AMD.¹³
- Healthy behaviors—People with a healthy diet who exercised and did not smoke, compared with people without these healthy behaviors, were 71% less likely to develop AMD.¹³
- Regular intake of age-related eye disease study (AREDS) formula (vitamins A, C, and E, and zinc) may reduce the risk of AMD.¹⁴

PROGNOSIS

Twenty-five percent to 33% of patients with early ARM (age-related maculopathy, a precursor to AMD) progressed over a 7-year period. Smoking, elevated C-reactive protein, and specific complement genotypes increase the risk of progression.⁴

FOLLOW-UP

Patients with ARM and AMD should have regular follow-up with an ophthalmologist.

PATIENT EDUCATION

- AMD can cause a loss of vision leading to an inability to read and drive, thereby affecting many activities of daily living.
- A healthy lifestyle may prevent development or progression of AMD.
- Treatment options are available that decrease the risk of vision loss.
- Most patients with AMD need to see an ophthalmologist regularly in addition to their primary care physician.

24 EYE TRAUMA—HYPHEMA

Heidi Chumley, MD

PATIENT STORY

A 22-year-old man was hit in the eye with a baseball and presented to the emergency department with eye pain and redness and decreased visual acuity. There was a collection of blood in his anterior chamber (**Figure 24-1**) and he was diagnosed with a hyphema. He was given an eye shield for protection, advised to take acetaminophen for pain, and counseled not to engage in sporting activities until his hyphema resolved. He saw his physician daily for the next 2 days, during which his vision improved. His hyphema resolved in 5 days.

INTRODUCTION

Hyphema, blood in the anterior chamber, can be seen following eye trauma or as a result of clotting disturbances, vascular abnormalities, or mass effects from neoplasms. Traumatic hyphema occurs more often in boys and men, often related to work or sports. Hyphema typically resolves in 5 to 7 days, but some cases are complicated by rebleeding.

EPIDEMIOLOGY

- Hyphema occurs in 17 to 20 per 100,000 persons per year in the United States.¹
- Sixty percent of hyphemas result from sports injuries.² Sports with higher risk for eye injuries include paintball, baseball/softball, basketball, soccer, fishing, ice hockey, racquet sports, fencing, lacrosse, and boxing.

ETIOLOGY AND PATHOPHYSIOLOGY

- A hyphema is a collection of blood, mostly erythrocytes, that layer within the anterior chamber.
- Trauma is the most common cause, often resulting from a direct blow from a projectile object such as a ball, air pellet or BB, rock, or fist.
- Direct force to the eye (blunt trauma) forces the globe inward, distorting the normal architecture.
- Intraocular pressure rises instantaneously causing the lens/iris/ciliary body to move posteriorly, thus disrupting the vascularization with resultant bleeding.
- Intraocular pressure continues to rise and bleeding stops when this pressure is high enough to compress the bleeding vessels.
- A fibrin-platelet clot forms and stabilizes in 4 to 7 days; this is eventually broken down by the fibrinolytic system and cleared through the trabecular meshwork.

FIGURE 24-1 Layering of red blood cells in the anterior chamber following blunt trauma. This grade 1 hyphema has blood filling in less than one-third of the anterior chamber. (Courtesy of Paul D. Comeau.)

DIAGNOSIS

The diagnosis of hyphema is clinical, depending on the classic appearance of blood layering in the anterior chamber.

CLINICAL FEATURES

History and physical:

- Layered blood in the anterior chamber.
- History of eye trauma or risk factor for nontraumatic hyphema.
- Increased intraocular pressure (32%).
- Decreased vision.
- Hyphemas are classified according to the amount of blood in the anterior chamber:¹
 - Grade 1: Less than one-third of the anterior chamber (see **Figure 24-1**); 58% of all hyphemas.
 - Grade 2: One-third to one-half of the anterior chamber; 20% of all hyphemas.
 - Grade 3: One-half to almost completely filled anterior chamber; 14% of all hyphemas.
 - Grade 4: Completely filled anterior chamber; 8% of all hyphemas.
- Eye trauma without hyphema (**Figure 24-2** and **24-3**) can lead to subconjunctival hemorrhage, anterior uveitis, and/or distortion of the normal architecture, including globe rupture.

LABORATORY TESTING (INCLUDE ANCILLARY TESTING, TOO)

- Consider laboratory tests to evaluate for bleeding disorders: Bleeding time, electrophoresis for sickle cell trait, platelet count, prothrombin and partial thromboplastin time, and liver tests.

IMAGING

- Consider CT imaging if a mechanism of injury suggests an associated orbital fracture or concern for orbital or intraocular foreign body.

DIFFERENTIAL DIAGNOSIS

Hyphema is an unmistakable physical examination finding that can be caused by any of the following:

- Trauma—History of trauma, including nonaccidental trauma (i.e., child abuse).
- Blood clotting disturbances—Personal or family history of bleeding disorder, little or no trauma, and black race (increased incidence of sickle trait and disease).
- Medication-induced anticoagulation—Chronic use of aspirin or warfarin and little or no trauma.
- Neovascularization—Diabetes with diabetic retinopathy, history of other ocular disease (central retinal vein occlusion), or history of prior eye surgery (cataract); without trauma, often painless, sudden, blurry vision.

FIGURE 24-2 This young patient was hit in the eye with the corner of a laminated name card. The sharp edge perforated the cornea and pulled a portion of the iris out of the wound. Note the abnormal configuration of the pupil (dyscoria). No hyphema noted. This patient required emergent surgical repair. (Reprinted with permission from Lo MW, Chalfin S. Retrobulbar anesthesia for repair of ruptured globes. *Am J Ophthalmol.* 1997;123(6):833-835. Photo by Paul D. Comeau.)

FIGURE 24-3 Subconjunctival hemorrhage and eyelid ecchymosis following accidental trauma. There was no hyphema present. (Courtesy of Richard P. Usatine, MD.)

- Melanoma or retinoblastoma—Variety of presentations depending on the size and location; hyphema occurs when mass effect shears the lens/iris/ciliary body causing bleeding.
- Abnormal vasculature, that is, juvenile xanthogranuloma—Red to yellow papules and nodules in the eyes, skin, and viscera, most often present by 1 year of age.

MANAGEMENT

- Most hyphemas resolve in 5 to 7 days; management strategies protect the eye and decrease complications, including rebleeding.
- Evaluate or refer for evaluation for elevated intraocular pressure and other associated injuries. Urgent referral if concern for globe rupture.

A recent Cochrane review evaluated these interventions: antifibrinolytic agents, corticosteroids, cycloplegics, miotics, aspirin, conjugated estrogens, eye patching, head elevation, and bed rest.

- No interventions had a significant effect on visual acuity.
- Aminocaproic acid (antifibrinolytic) use resulted in a slower resolution of the primary hyphema.
- Antifibrinolytics: aminocaproic acid, tranexamic acid, and aminomethylbenzoic acid reduced the rate of secondary hemorrhage.³

NONPHARMACOLOGIC

- Eye patching, head elevation, and bed rest do not independently affect visual acuity. However, experts recommend to patch and shield the injured eye and allow the patient to remain ambulatory as part of a comprehensive treatment plan.¹ **SOR C**

MEDICATIONS

- Although controversy remains about the best treatment, each of the following has been demonstrated to lower the risk of rebleeding in randomized-controlled trials:
 - Oral antifibrinolytic agents (aminocaproic acid 50 mg/kg every 4 hours for 5 days, not to exceed 30 g/day, or tranexamic acid 75 mg/kg per day divided into 3 doses).⁴ **SOR C**
 - Topical aminocaproic acid (30% in a gel vehicle 4 times a day) is as effective as oral.⁴ **SOR C**
 - Avoid aspirin and NSAIDs, which have been associated with higher rates of rebleeding.
 - Use acetaminophen, if needed, for pain.

REFERRAL OR HOSPITALIZATION

- Signs of a violated globe, such as a perforation of the cornea, conjunctiva or sclera, distorted ocular architecture, or exposed and/or distorted uveal tissue such as the iris (causing a peaked pupil), require immediate surgical evaluation and repair (see **Figure 24-2**).
- Surgical intervention has been recommended for patients with persistent total hyphema or prolonged elevated intraocular pressure.
- Outpatient management is acceptable for adults and children if patient is likely to be able to follow treatment plan.^{4,5} **SOR B**

PREVENTION

Ninety percent of sports-related eye injuries can be prevented with appropriate eyewear.⁶

PROGNOSIS

The percentage of patients who regain 20/40 vision varies by severity of the hyphema: grade I, 80%; grade III, 60%; grade IV, 35%.¹

FOLLOW-UP

Patients should be monitored daily for the first 5 or more days by a provider familiar with caring for hyphemas. Patient with a hyphema should be followed subsequently for signs of angle recession and high intraocular pressure, which predisposes the patient to traumatic glaucoma, an insidious cause of blindness in patients with a history of trauma.

PATIENT EDUCATION

- Complications include rebleeding, decreased visual acuity, posterior or peripheral anterior synechiae, corneal bloodstaining, glaucoma, and optic atrophy. Patients may need surgical or medical management for glaucoma.
- Patients who are more likely to rebleed include black patients (irrespective of sickle cell/trait status),^{7,8} patients with a grade 3 or 4 hyphema, and patients with high initial intraocular pressure.
- Warn patients that they may have angle recession from traumatic causes of the hyphema. This will predispose the patient to a lifetime risk of traumatic glaucoma, which can cause blindness without any symptoms. These patients need to be monitored regularly by an ophthalmologist for increased pressure and glaucomatous nerve changes.

25 DIFFERENTIAL DIAGNOSIS OF THE RED EYE

Heidi Chumley, MD
Richard P. Usatine, MD

PATIENT STORY

A 41-year-old man wakes up with eyes that are reddened bilaterally (**Figure 25-1**). He has some burning and itching in the eyes, but no pain. He describes minimal crusting on his eyelashes. Examination shows no loss of vision, no foreign bodies, and pupils that are equal, round, and reactive to light. He is diagnosed with viral conjunctivitis, which does not require antibiotic treatment. He is advised about methods to prevent spreading conjunctivitis to others and is asked to notify the physician immediately if he experiences eye pain or loss of vision. He recovers spontaneously without complications after a few days.

INTRODUCTION

A red eye signifies ocular inflammation. The differential diagnosis includes both benign and sight-threatening conditions. The pattern of redness; presence/absence of eye pain or photophobia, vision loss, or eye discharge; involvement of cornea; and visual acuity are helpful in differentiating among causes (see **Table 25-1**). Although most red eyes seen in the primary care setting are a result of viral conjunctivitis, several causes of red eye require urgent referral.

EPIDEMIOLOGY

- An acute red eye or eyes is a common presentation in ambulatory and emergency departments.
- Conjunctivitis is the most common cause of a nontraumatic red eye in primary care.

ETIOLOGY AND PATHOPHYSIOLOGY

Red eye is caused by any of the following:

- Infectious or noninfectious inflammation of any layer of the eye (conjunctivitis, episcleritis, scleritis, uveitis, keratitis).
- Eyelid pathology (blepharitis, entropion, i.e., inward turning of the eyelid, or other eyelid malposition).
- Acute glaucoma (usually angle closure).
- Trauma.
- Subconjunctival hemorrhage.

FIGURE 25-1 Bilateral viral conjunctivitis in a 41-year-old man. (Courtesy of Richard P. Usatine, MD.)

TABLE 25-1 Clinical Features in the Diagnosis of Red Eye

	Conjunctivitis	Episcleritis	Scleritis	Uveitis	Keratitis	Closed-Angle Glaucoma	Subconjunctival Hemorrhage	Ocular Rosacea
Redness	Diffuse	Segmental; pink	Segmental or diffuse; dark red, purple, or blue	360-Degree per- ilimbal (worse at limbus)	Diffuse, ciliary injection	Diffuse, scleral	Blotchy, outside vessels	Diffuse
Eye pain	No	Mild, may be tender to touch	Severe, boring	Sometimes	Usually	Yes	No, unless caused by trauma	No
Vision loss	No	No	Sometimes	Sometimes	Maybe, depend- ing on location	Yes	No	In severe cases
Discharge	Usually	No	No	No	Maybe	No	No	No
Photopho- bia*	No	No	Yes	Yes, if anterior	Yes	Yes	No	Sometimes
Pupil	Normal	Normal	Normal	Constricted	Normal to con- stricted	Mild dilation, less re- sponsive	Normal; unless affected by trauma	Normal
Cornea	Clear	Clear	Clear	Clear to hazy	Hazy	Usually hazy	Clear	Clear or neo- vasculariza- tion, cloudy
Associated diseases	URI, allergy, exposure	Occasional systemic disease	Systemic disease	Systemic dis- ease, idio- pathic	Contact lenses, HSV or vari- cella, rosacea	Causes head- aches, nau- sea, vomit- ing, GI symptoms	HTN, trauma, Valsalva, cough, blood thinners	Acne rosacea (can exist without also), blepharitis

Abbreviations: HSV, Herpes simplex virus; HTN, hypertension; URI, upper respiratory infection.

*For identifying serious causes of red eye, the presence of photophobia elicited with a penlight in a general practice had a positive predictive value of 60% and a negative predictive value of 90%.¹

DIFFERENTIAL DIAGNOSIS

An acute red eye can be caused by any of the following:

- **Conjunctivitis**—Conjunctival injection, eye discharge, gritty or uncomfortable feeling, and no vision loss (**Figures 25-1 to 25-4**) (see also Chapter 16, Conjunctivitis).
- **Episcleritis**—Segmental or diffuse inflammation of episclera (pink color), mild or no discomfort, but can be tender to palpation, and no vision disturbance (**Figure 25-5**) (see also Chapter 17, Episcleritis and Scleritis).
- **Scleritis**—Segmental or diffuse inflammation of sclera (dark red, purple, or blue color), severe boring eye pain often radiating to head and neck, and photophobia and vision loss (**Figure 25-6**) (see also Chapter 17, Episcleritis and Scleritis).
- **Keratitis or corneal ulcerations**—Diffuse erythema with ciliary injection often with pupillary constriction; eye discharge; and pain, photophobia, vision loss depending on the location of ulceration (**Figure 25-7**). Often associated with the use of contact lenses.
- **Subconjunctival hemorrhage** (**Figure 25-8**)—Bright red subconjunctival blood; usually not painful; can present after significant coughing/sneezing, after trauma, or in the setting of dry eyes with minor trauma from rubbing with a finger. Not vision-threatening.
- **Ocular rosacea**—Eye findings present in more than 50% of people with facial rosacea. Can present as blepharitis, conjunctivitis, or episcleritis or cause corneal ulcerations and neovascularization (**Figures 25-9 and 25-10**).
- **Uveitis or Iritis**—A 360-degree injection, which is most intense at the limbus, eye pain, photophobia, and vision loss (**Figure 25-11**) (see also Chapter 18, Uveitis and Iritis).
- **Trauma causing globe injury, or hemorrhage into the anterior chamber called hyphema** (**Figures 25-12 and 25-13**) (see Chapter 24, Eye Trauma—Hyphema).
- **Pterygium**—Fibrovascular tissue on the surface of the eye extending onto the cornea (**Figure 25-14**) (see also Chapter 12, Pterygium).
- **Hypopyon** is a term for visible white cells (pus) layered out in the anterior chamber. It may be caused by inflammation of the iris or an eye infection. The inflammation and/or infection also causes the conjunctiva and sclera to become red (**Figure 25-15**).
- **Acute-angle closure glaucoma**—Cloudy cornea and scleral injection, shallow anterior chamber (check other eye if difficult to assess chamber depth in the red eye), eye pain with ipsilateral headache, and severe vision loss (see also Chapter 19, Glaucoma).
- **Eyelid pathology**—Blepharitis (inflammation of the eyelid) (**Figure 25-16**). Entropion is a turning inward of the eyelid and can cause irritation to the conjunctiva and cornea.

MANAGEMENT

Treatment for specific causes is discussed in the corresponding chapters.

Refer patients with any of the following to an ophthalmologist:^{2,3}

SOR 

- Visual loss.
- Moderate or severe pain.

- Severe, purulent discharge.
- Corneal involvement.
- Conjunctival scarring.
- Lack of response to therapy.
- Topical steroid therapy.
- Recurrent episodes.
- Open globe or perforation.
- History of herpes simplex virus (HSV) eye disease.
- History of contact lens wear.

PROGNOSIS

Prognosis depends on underlying cause (see corresponding chapters).

FOLLOW-UP

Timing of follow-up and need for further testing is determined by the underlying cause (see corresponding chapters).

PATIENT EDUCATION

Advise patients to notify their physician immediately for eye pain (other than gritty discomfort) and/or loss of vision.

SECTION 1 EAR

26 OTITIS MEDIA: ACUTE
OTITIS AND OTITIS
MEDIA WITH EFFUSION

Brian Z. Rayala, MD

PATIENT STORY

A 15-month-old boy is brought by both parents to his family physician with a 2-day history of fever, irritability, and frequent tugging of his left ear. This was preceded by a 1-week history of nasal congestion, cough, and rhinorrhea. On otoscopy, his left tympanic membrane (TM) appears erythematous, cloudy, bulging, and exudative (**Figure 26-1**). His left TM fails to move on pneumatic otoscopy. The physician diagnoses acute otitis media and decides with the parents to prescribe a 10-day course of amoxicillin; the child recovers uneventfully.

In follow-up 2 months later, the child appears healthy and is meeting all his developmental milestones. On otoscopic examination, air–fluid levels are seen in the right ear (**Figure 26-2**). The physician explains the diagnosis of otitis media with effusion to the parents and arranges follow-up. Three months later the effusion is completely resolved.

INTRODUCTION

Acute otitis media (AOM) is the most common diagnosis for acute office visits for children.¹ AOM is characterized by middle-ear effusion in a patient with signs and symptoms of acute illness (e.g., fever, irritability, otalgia). Otitis media with effusion (OME) is a disorder characterized by fluid in the middle ear in a patient without signs and symptoms of acute ear infection; it is also very common in childhood.

EPIDEMIOLOGY

- AOM accounted for \$5 billion of the total national health expenditure in 2000; more than 40% was incurred for children between 1 and 3 years of age.¹
- It is estimated that 60% to 80% of children in the United States develop AOM by 1 year of age and that 80% to 90% develop AOM by 2 to 3 years of age.^{2,3}
- The highest incidence occurs between 6 and 24 months of age.^{2,3}
- AOM is the most common reason for outpatient antibiotic treatment in the United States.⁴ A national survey in 1992 revealed that 30% of all antibiotics prescribed for children younger than age 18 years was for treatment of AOM.⁵
- OME is diagnosed in 2.2 million children yearly in the United States.⁶

FIGURE 26-1 Acute otitis media in the left ear of a 15-month-old patient with marked erythema and bulging of the tympanic membrane. The malleus and light reflex are not visible. (Courtesy of William Clark, MD.)

FIGURE 26-2 Otitis media with effusion (OME) in the right ear. Note multiple air–fluid levels in this slightly retracted, translucent, nonerythematous tympanic membrane. (Courtesy of Frank Miller, MD.)

- Approximately 90% of children (80% of individual ears) have OME at some time before school age, most often between ages 6 months and 4 years.⁶
- The combined direct and indirect health care costs of OME amount to \$4 billion annually.⁶

ETIOLOGY AND PATHOPHYSIOLOGY

AOM is often preceded by upper respiratory symptoms such as cough and rhinorrhea.

- Pathogenesis of AOM includes:⁷
 - Eustachian tube dysfunction (usually a result of an upper respiratory infection) and subsequent tube obstruction.
 - Increased negative pressure in the middle ear.
 - Accumulation of middle-ear fluid.
 - Microbial growth.
 - Suppuration (that leads to clinical signs of AOM).
- Most common pathogens in the United States and United Kingdom are:^{8,9}
 - Strains of *Streptococcus pneumoniae* not in the heptavalent pneumococcal vaccine (PCV7) (after introduction of PCV7 vaccine in 2000).
 - Nonencapsulated (nontypable) *Haemophilus influenzae* (NTHi).
 - *Moraxella catarrhalis*.
 - *Staphylococcus aureus*.
- Viruses account for 16% of cases. Respiratory syncytial viruses, rhinoviruses, influenza viruses, and adenoviruses have been the most common isolated viruses.¹⁰

OME most commonly follows AOM; it may also occur spontaneously.

- Fluid limits sound conduction through the ossicles and results in decreased hearing.
- Reasons for the persistence of fluid in otitis media remain unclear, although potential etiologies include allergies, biofilm, and physiologic features.
- “Glue ear” refers to extremely viscous mucoid material within the middle ear and is a distinct subtype of OME.

RISK FACTORS

- The most important risk factors for AOM include young age and attendance at daycare centers.
- Other risk factors include:¹¹
 - White race.
 - Male gender.
 - History of enlarged adenoids, tonsillitis, or asthma.
 - Multiple previous episodes.
 - Bottle feeding.
 - History of ear infections in parents or siblings.
 - Use of a soother or pacifier.
- Second-hand smoke is a risk factor when parents smoke at home.
- Risk factors for OME include age 6 years or younger, large number of siblings, low socioeconomic group, frequent upper respiratory tract infection, tobacco exposure, daycare attendance, and bottle feeding.¹²

FIGURE 26-3 Otitis media with effusion in the left ear showing retraction of the TM and straightening of the handle of the malleus as the retraction pulls the bone upward. (Courtesy of Glen Medellin, MD.)

DIAGNOSIS

CLINICAL FEATURES OF AOM

- To diagnose AOM, the clinician should confirm a history of acute onset, identify signs of middle-ear effusion (MEE), and evaluate for the presence of signs and symptoms of middle-ear inflammation.⁶ **SOR** 
- Elements of the definition of AOM are *all* of the following:⁶
 - Recent, usually abrupt, onset of signs and symptoms of middle-ear inflammation and MEE.
 - The presence of MEE. Although MEE is often presumed by bulging of the TM (**Figure 26-1**) or air–fluid level behind the TM (**Figure 26-2**), the guideline stresses use of objective measures of confirming MEE such as:⁶
 - Limited or absent mobility of the TM established by pneumatic otoscopy—The TM does not move during air insufflation; often initially seen as retraction of the TM (**Figures 26-3** and **26-4**).
 - Objective measures such as tympanometry.
 - Otorrhea.
 - Signs or symptoms of middle-ear inflammation as indicated by either:
 - Distinct erythema of the TM (**Figure 26-1**) in contrast to the normal TM (**Figure 26-5**), or
 - Distinct otalgia (discomfort clearly referable to the ear[s] that results in interference with or precludes normal activity or sleep).

CLINICAL FEATURES OF OME

- The most common symptom, present in more than half of patients, is mild hearing loss. This is usually identified when parents express concern regarding their child's behavior, performance at school, or language development.¹²
- Absence of signs and symptoms of acute illness assists in differentiating OME from AOM.
- Common otoscopic findings include:
 - Air–fluid level or bubble (**Figure 26-2**).
 - Cloudy TM (**Figures 26-4** and **26-6**) in contrast to the normal TM (**Figure 26-5**).
 - Redness of the TM may be present in approximately 5% of ears with OME.
- Clinicians should use pneumatic otoscopy as the primary diagnostic method for OME **SOR** **A**.¹³
 - Impaired mobility of the TM is the hallmark of MEE.
 - According to a metaanalysis, impaired mobility on pneumatic otoscopy has a pooled sensitivity of 94% and specificity of 80%, and positive likelihood ratio of 4.7 and negative likelihood ratio of 0.075.¹³

LABORATORY TESTS AND IMAGING

- Because AOM and OME are clinical diagnoses, diagnostic testing has a limited role. When clinical presentation and physical examination (including otoscopy) do not establish the diagnosis, the following can be used as adjunctive techniques:
 - Tympanometry—This procedure records compliance of the TM by measuring reflected sound. AOM and OME will plot as a reduced or flat waveform. This technique requires patient cooperation but provides more objective data.

FIGURE 26-4 Early acute otitis media at the stage of eustachian tube obstruction. Note the slight retraction of the TM, the more horizontal position of the malleus, and the prominence of the lateral process. (Courtesy of William Clark, MD.)

FIGURE 26-5 Acute otitis media, stage of suppuration. Note presence of purulent exudate behind the TM, the outward bulging of the TM, prominence of the posterosuperior portion of the drum, and generalized TM edema. The white area is tympanosclerosis from a previous infection. (Courtesy of William Clark, MD.)

- Acoustic reflectometry—This procedure, very similar to tympanometry, measures sound reflectivity from the middle ear. With this test, the clinician is able to distinguish air- or fluid-filled space without requiring an airtight seal of the ear canal.
- Middle ear aspiration—For patients with AOM, aspiration may be warranted if patient is toxic, is immunocompromised, or has failed prior courses of antibiotics.

DIFFERENTIAL DIAGNOSIS

The key differentiating feature between AOM and OME is the absence of signs and symptoms of acute illness in OME (e.g., fever, irritability, otalgia). Otoscope findings may be similar. Other clinical entities that may be confused with AOM and OME include:

- Otitis externa—Otitis externa presents with otalgia, otorrhea and mild hearing loss, all of which can be present in AOM. Tragal pain on physical exam and signs of external canal inflammation on otoscopic exam differentiate it from AOM. Careful ear irrigation if tolerated may be helpful to visualize the TM to differentiate otitis externa from AOM (see Chapter 27, Otitis Externa).
- Otic barotrauma—This often presents with severe otalgia. Key historical features include recent air travel, scuba diving, or ear trauma, preceded by an upper respiratory infection.
- Cholesteatoma—Unlike AOM, this is a clinically silent disease in its initial stages. Presence of white keratin debris in the middle ear cavity (on otoscopy) is diagnostic (Figures 26-7 and 26-8).
- Foreign body—A foreign body may present with otalgia. Otoscopy reveals presence of foreign body (see Chapter 28, Ear: Foreign Body).
- Bullous myringitis—Bullous myringitis is often associated with viral or mycoplasma infection as well as usual AOM pathogens; in approximately one-third of patients, there is a component of sensorineural hearing loss. Otoscopy shows serous-filled bulla on the surface of the TM (Figure 26-9). Patients present with severe otalgia.
- Chronic suppurative otitis media (CSOM)—Otoscopy shows TM perforation and otorrhea; history reveals a chronically draining ear and recurrent middle-ear infections with or without hearing loss.
- Referred otalgia—This is rare in children and in cases of bilateral otalgia. Should be considered in cases of otalgia that do not fit clinical features of AOM. Referred pain usually from other head and neck structures (e.g., teeth, jaw, cervical spine, lymph and salivary glands, nose and sinuses, tonsils, tongue, pharynx, meninges).
- Mastoiditis—Mastoiditis may be differentiated from simple AOM by presence of increasing pain and tenderness over mastoid bone in a patient with AOM who has not been treated by antibiotics, or recurrence of mastoid pain and tenderness in patients treated with antibiotics. Recurrence or persistence of fever, as well as progressive otorrhea, are other historical clues. The mastoid swelling may cause the pinna to protrude further than normal (Figure 26-10).
- Traumatic perforation of the TM (Figure 26-11)—A hole in the TM is seen without purulent drainage.

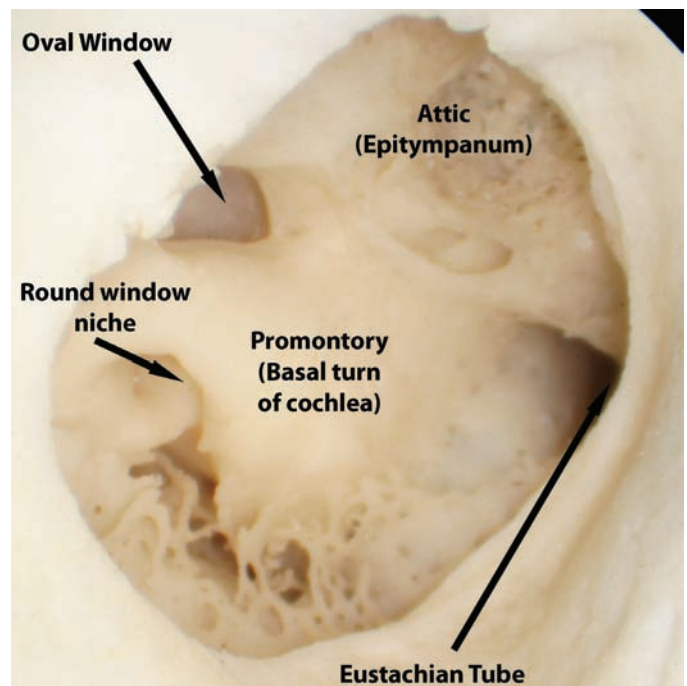

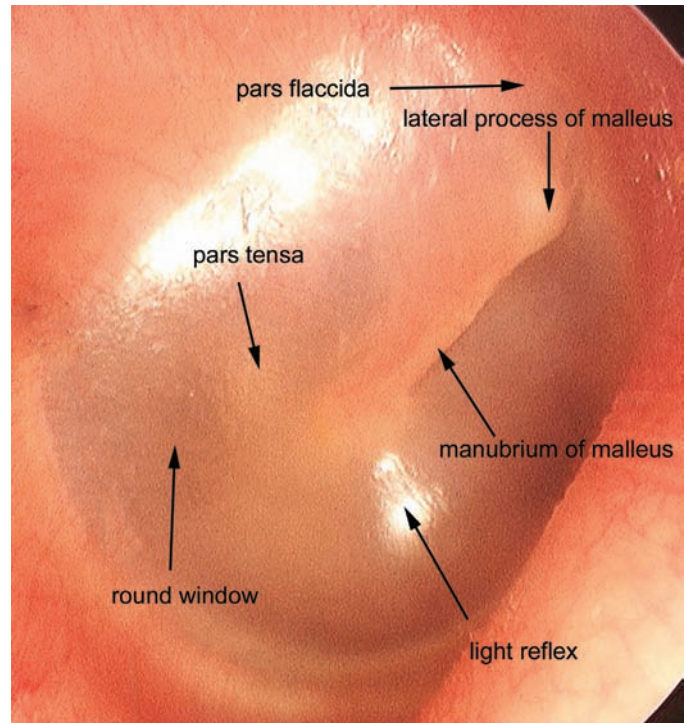

FIGURE 26-6 Normal right tympanic membrane with comparison using normal bony landmarks of the inner ear. The ossicles were removed in this dissection. (Courtesy of William Clark, MD.)

MANAGEMENT

NONPHARMACOLOGIC

Antibiotics are not necessary to treat uncomplicated AOM in an otherwise healthy child.¹⁴ **SOR A**

Management of OME primarily consists of watchful waiting. Most cases resolve spontaneously within 3 months; only 5% to 10% last 1 year or longer. Treatment depends on duration and associated conditions. The following options should be considered:

- Document the laterality, duration of effusion, and presence and severity of associated symptoms at each assessment of the child with OME.⁶ **SOR C**
- Distinguish the child with OME who is at risk for speech, language, or learning problems from other children with OME and more promptly evaluate hearing, speech, language, and need for intervention in children at risk.⁶ **SOR C** Risk factors for developmental difficulties include:
 - Permanent hearing loss independent of OME.
 - Suspected or diagnosed speech and language delay or disorder.
 - Autism-spectrum disorder and other pervasive developmental disorders.
 - Syndromes (e.g., Down syndrome) or craniofacial disorders that include cognitive, speech, and language delays.
 - Blindness or uncorrectable visual impairment.
 - Cleft palate with or without associated syndrome.
 - Developmental delay.
- Manage the child with OME who is not at risk with watchful waiting for 3 months from the date of effusion onset (if known) or diagnosis (if onset is unknown).⁶ **SOR B**
- Hearing testing is recommended when OME persists for 3 months or longer or at any time if language delay, learning problems, or significant hearing loss is suspected in a child with OME.⁶ **SOR B**
- Autoinflation with nasal balloon, in one systematic review, provided short-term benefits, although 12% of children ages 3 to 10 years were unable to use it.¹²

MEDICATIONS

- Oral acetaminophen (paracetamol) and ibuprofen may reduce earache when given with antibiotics.¹⁵ There is insufficient data to evaluate the effectiveness of topical analgesics in AOM.¹⁶ **SOR B**
- Antibiotics seem to be most beneficial in children younger than 2 years of age with bilateral AOM, high fever, or vomiting, and in children with both AOM and otorrhea. For most other children with mild disease, an observational policy seems justified.^{14,17} **SOR B**
- Antibiotics may lead to more rapid reduction in symptoms of AOM, but increase the risk of adverse effects, including diarrhea, vomiting, and rash.¹⁵ **SOR B**
 - Antibiotics seem to reduce pain at 2 to 7 days, and may prevent development of contralateral AOM, but increase the risks of adverse effects compared with placebo.¹³
 - There is insufficient effectiveness data regarding which antibiotic regimen is better than another.^{13,15}

FIGURE 26-7 Cholesteatoma. (Courtesy of Vladimir Zlinsky, MD, in Roy F. Sullivan, PhD. *Audiology Forum: Video Otoscopy*, www.rcsullivan.com.)

FIGURE 26-8 Primary acquired cholesteatoma with debris removed from the attic retraction pocket. (Courtesy of William Clark, MD.)

- Antibiotics found to be effective in AOM include amoxicillin, amoxicillin/clavulanic acid, ampicillin, penicillin, erythromycin, azithromycin, trimethoprim-sulfamethoxazole, and cephalosporins. Amoxicillin is a good first-line treatment because it is inexpensive and children tolerate the bubblegum taste well.
- Longer (8- to 10-day) courses of antibiotics reduce short-term treatment failure but have no long-term benefits compared with shorter regimens (5-day courses).^{15,18}
- An observational approach substantially reduces unnecessary use of antibiotics in children with AOM and may be an alternative to routine use of antimicrobials for treatment of such children.¹⁹
- Immediate antibiotic treatment (i.e., given at initial consultation) may reduce the duration of symptoms of AOM, but increases the risk of vomiting, diarrhea, and rash compared with delayed treatment (i.e., given after 72 hours).¹⁵ **SOR B**
- Treatment of AOM with decongestants and antihistamines is not recommended.²⁰ **SOR B**
- Antihistamines and decongestants are not effective for OME.⁶ **SOR A**
- Antimicrobials and corticosteroids are not recommended for OME.⁶ **SOR A**

FIGURE 26-9 Bullous myringitis can be differentiated from otitis media with effusion by identifying serous-filled bulla on the surface of the TM. (Courtesy of Vladimir Zlinsky, MD, in Roy F. Sullivan, PhD. *Audiology Forum: Video Otoscopy*, www.rcsullivan.com.)

COMPLEMENTARY AND ALTERNATIVE THERAPY

- Evidence on whether zinc supplementation can reduce the incidence of otitis media in healthy children younger than the age of 5 years living in low- and middle-income countries is mixed.²¹ **SOR B**

REFERRAL

- Refer to specialist (otolaryngologist, audiologist, or speech-language pathologist) if:⁶ **SOR C**
 - Persistent fluid for 4 or more months with persistent hearing loss.
 - Associated speech delay.
 - Structural damage to TM or middle-ear.
- Tympanostomy tubes for children with recurrent AOM (3 or more episodes of AOM in 6 months, or 4 or more AOM in 1 year) have a significant role in maintaining a “disease-free” state in the first 6 months after insertion. Because long-term effectiveness is uncertain, clinicians should consider possible adverse effects before surgery is undertaken.²² **SOR B**
- Insertion of tympanostomy tubes in young children with persistent middle-ear infection does not improve cognitive development, language acquisition, or speech development compared with waiting 6 to 9 months for the effusion to resolve before placing the tubes.²³ Moreover, delayed insertion of tubes helps children avoid getting tubes altogether and does not result in worse developmental outcomes.²⁴ **SOR A**
- When a child becomes a surgical candidate, tympanostomy tube insertion is the preferred initial procedure; adenoidectomy should not be performed unless a distinct indication exists (e.g., nasal obstruction, chronic adenoiditis).⁶ **SOR B**
- Repeat surgery consists of adenoidectomy plus myringotomy, with or without tube insertion. Tonsillectomy alone or myringotomy alone should not be used to treat OME.⁶ **SOR B**

PREVENTION

- The currently licensed PCV7 administered during infancy has marginal beneficial effects for the prevention of AOM.²⁵ Although PCV7 only confers a marginal decrease in AOM episodes for the individual, it may still have a substantial impact on the healthcare burden of AOM. Administering PCV7 in older children with a history of AOM appears to have no benefit in preventing further episodes.²⁵ **SOR A**
- For children at risk, antibiotics given once or twice daily reduces the probability of AOM while the child is on treatment. In similar populations, antibiotics reduce the number of episodes of AOM per year from around 3 to around 1.5. Although this appears as a marginal reduction for the individual, it may have larger absolute benefits from a population standpoint. These benefits need to be balanced with the increased risks of vomiting, diarrhea, and rash.^{15,26} **SOR A**
- Xylitol chewing gum or syrup given 5 times daily has a small preventive effect on recurrence of AOM, but the compliance issues in giving a medicine to such young children 5 times daily render it an unrealistic treatment option.¹⁵ **SOR B**
- Tympanostomy tubes lead to short-term reduction in the number of episodes of AOM but increase the risk of complications (i.e., tympanosclerosis; **Figures 26-12 and 26-13**).¹⁵ **SOR B**

PROGNOSIS

- Without antibiotics, AOM resolves within 24 hours in approximately 60% of children and within 3 days in approximately 80% of children. Rate of suppurative complications if antibiotics are withheld is 0.13%.²⁷
- Most cases of OME resolve spontaneously within 3 months; only 5% to 10% last 1 year or longer. However, effusion will recur in 30% to 40% of patients.⁶

FOLLOW-UP

- If a patient with AOM fails to respond to the initial management option within 48 to 72 hours, the clinician should reassess the patient to confirm AOM and exclude other causes of illness. If AOM is confirmed in a patient initially managed with observation, the clinician should begin antibiotics. If the patient was initially managed with antibiotics, the clinician should change antibiotics.⁶ **SOR B**
- Potentially serious complications of AOM, such as mastoiditis or facial nerve involvement, require urgent referral.
- There is no consensus in the medical community regarding timing of posttreatment follow-up of AOM or who should be receiving follow-up. There is some evidence that parents can be reliable predictors in the resolution or persistence of AOM following antibiotic treatment.²⁸
- Children with persistent OME who are not thought to be at significant risk should be reexamined at 3- to 6-month intervals until the effusion is gone, significant hearing loss is identified, or structural abnormalities of the eardrum or middle ear are suspected.⁶ **SOR B**

FIGURE 26-10 A. Mastoiditis in a young boy with recurrent otitis media. Note the erythema and swelling behind the ear. The ear is sticking out more than the other side. B. Surgical drainage was performed. (Courtesy of William Clark, MD.)

PATIENT EDUCATION

- Patient education should focus on identification, prevention, and control of risk factors (see above).
- Parents should be made aware of the high rates of spontaneous resolution of AOM and potential adverse effects of antibiotics. Providing a prescription for an antibiotic at the initial visit but advising delay of initiation of medication (i.e., observational approach for up to 48 hours) is an alternative to immediate treatment and is associated with lower antibiotic use.¹⁹
- Patients should be informed that the natural history of OME is spontaneous resolution.
 - Periodic follow-up to monitor resolution of MEE is extremely important.
 - If MEE is persistent and signs and symptoms of hearing loss, language difficulties, and learning problems arise, additional treatment may be considered.

27 OTITIS EXTERNA

Brian Z. Rayala, MD

PATIENT STORY

A 40-year-old woman with type 2 diabetes presents to her family physician with a 2-day history of bilateral otalgia, otorrhea, and hearing loss. Symptoms started in the right ear and then rapidly spread to the left ear. She had a low-grade fever and was systemically ill. The external ear was swollen with honey-crusts (**Figures 27-1** and **27-2**). The external auditory canal (EAC) was narrowed and contained purulent discharge (**Figure 27-3**). Ear, nose, and throat (ENT) was consulted and she was admitted to the hospital for the presumptive diagnosis of malignant otitis externa. The MRI showed some destruction of the temporal bone. She was started on IV ciprofloxacin and the ear culture grew out *Pseudomonas aeruginosa* sensitive to ciprofloxacin. The patient responded well to treatment and was able to go home on oral ciprofloxacin 5 days later.

INTRODUCTION

Otitis externa (OE) is common in all parts of the world. OE is defined as inflammation, often with infection, of the EAC.¹

EPIDEMIOLOGY

- Incidence of OE is not known precisely; its lifetime incidence was estimated at 10% in one study.²
- Occurs more in adults than in children.

ETIOLOGY AND PATHOPHYSIOLOGY

- Common pathogens, which are part of normal EAC flora, include aerobic organisms predominantly (*P. aeruginosa* and *Staphylococcus aureus*) and, to a lesser extent, anaerobes (*Bacteroides* and *Peptostreptococcus*). Up to a third of infections are polymicrobial. A small proportion (2% to 10%) of OE is caused by fungal overgrowth (e.g., *Aspergillus niger* usually occurs with prolonged antibiotic use).¹
- Pathogenesis of OE includes the following:
 - Trauma, the usual inciting event, leads to breach in the integrity of EAC skin.
 - Skin inflammation and edema ensue, which, in turn, leads to pruritus and obstruction of adnexal structures (e.g., cerumen glands, sebaceous glands, and hair follicles).
 - Pruritus leads to scratching, which results in further skin injury.
 - Consequently, the milieu of the EAC is altered (i.e., change in quality and quantity of cerumen, increase in pH of EAC, and dysfunctional epithelial migration).
 - Finally, the EAC becomes a warm, alkaline, and moist environment—ideal for growth of different pathogens.

FIGURE 27-1 Malignant/necrotizing otitis externa in a 40-year-old woman with diabetes. Note the swelling and honey-crusts of the pinna. The EAC and temporal bone were involved. (Courtesy of E.J. Mayeaux, MD.)

FIGURE 27-2 Another view of the malignant/necrotizing otitis externa. (Courtesy of E.J. Mayeaux, MD.)

RISK FACTORS³

- Environmental factors:
 - Moisture—Macerates skin of EAC, elevates pH, and removes protective cerumen layer (from swimming, perspiration, high humidity).
 - Trauma—Leads to injury of EAC skin (from cotton buds, fingernails, hearing aids, ear plugs, paper clips, match sticks, mechanical removal of cerumen).
 - High environmental temperatures.
- Host factors:
 - Anatomical—Wax and debris accumulate and lead to moisture retention (e.g., a narrow ear canal, hairy ear canal).
 - Cerumen—Absence or overproduction of cerumen (leads to loss of the protective layer and moisture retention, respectively).
 - Chronic dermatologic disease (e.g., atopic dermatitis, psoriasis, seborrheic dermatitis).
 - Immunocompromise (e.g., chemotherapy, HIV, AIDS).

DIAGNOSIS

CLINICAL FEATURES

- OE can either be localized, like a furuncle, or generalized (**Figure 27-4**). The latter is known as “diffuse OE,” or simply OE. Seborrheic dermatitis of the external ear and EAC can be diffuse or generalized (see **Figure 27-4**).
- Forms of (diffuse) OE:¹
 - Acute (<6 weeks; **Figures 27-5** and **27-6**).
 - Chronic (>3 months)—May cause hearing loss and stenosis of the EAC (**Figure 27-7**).
 - Necrotizing or malignant form—Defined by destruction of the temporal bone, usually in diabetics or immunocompromised people; often life-threatening (see **Figure 27-1**).
- Key historical features include:
 - Otagia, including pruritus.
 - Otorrhea (see **Figure 27-3**).
 - Mild hearing loss.
- Key physical findings include:
 - Pain with tragal pressure or pain when the auricle is pulled superiorly; this may be absent in very mild cases.
 - Signs of EAC inflammation (edema, erythema, aural discharge) (see **Figures 27-5** through **27-7**).
 - Fever, periauricular erythema, and lymphadenopathy point to severe disease.
 - Complete obstruction of EAC occurs in advanced OE.
- Establishing the integrity of the tympanic membrane (TM) (through direct visualization) and the absence of middle-ear effusion (through pneumatic otoscopy) is crucial in differentiating OE from other diagnoses (e.g., suppurative otitis media, cholesteatoma).

LABORATORY AND IMAGING

- Because OE is mostly a clinical diagnosis, diagnostic testing has a limited role. When a patient fails to respond to empiric treatment,

FIGURE 27-3 Chronic suppurative otitis media with purulent discharge chronically draining from the ear of this 25-year-old man. This image could be seen in acute otitis media with perforation of the tympanic membrane or in a purulent otitis externa. (Courtesy of Richard P. Usatine, MD.)

FIGURE 27-4 Seborrheic dermatitis causing erythema and greasy scale of the external ear and ear canal. The seborrheic dermatitis itself causes breaks in the skin and the coexisting pruritus may lead the patient to damage their own ear canal. All this can become secondarily infected. (Courtesy of Eric Kraus, MD.)

obtaining a culture of aural discharge may help guide proper choice of treatment (antibacterial vs. antifungal agents).

- If necrotizing or malignant OE is suspected, CT or MRI of the ear/skull base is warranted.

DIFFERENTIAL DIAGNOSIS

- Chronic suppurative otitis media—Otoscopy shows TM perforation; history reveals a chronically draining ear and recurrent middle-ear infections with or without hearing loss (see **Figure 27-3**).
- Seborrheic dermatitis involving the external ear and EAC can lead to inflammation and breaks in the skin (see **Figure 27-4**). The coexisting pruritus may lead the patient to damage their own ear canal. This can all become secondarily infected and become an infected OE.
- Acute otitis media with perforated TM—Presents with purulent drainage from the canal in the setting of ear pain and clinical signs or symptoms of acute illness such as fever. If the TM is visible, it will be red with a perforation.
- Foreign body in the EAC—Otoscopy, with or without aural toilet, confirms presence of foreign body (that incites an inflammatory response, leading to otalgia and otorrhea); see Chapter 28, Ear: Foreign Body.
- Otitomycosis—Pruritus is generally more prominent and EAC inflammation (otalgia and otorrhea) is less pronounced; fungal organisms have a characteristic appearance in the EAC.
- Contact dermatitis—Usually caused by ototopical agents (e.g., neomycin, benzocaine, propylene glycol); seen in patients with poor response to empiric OE treatment; prominent clinical features include pruritus, erythema of conchal bowl, crusting, and excoriations.

MANAGEMENT

NONPHARMACOLOGIC

- The effectiveness of ear cleaning is unknown.³ **SOR B**
- The effectiveness of specialist aural toilet (use of operating microscope to mechanically remove material from external canal) for treating OE is unknown.¹ **SOR B**

MEDICATIONS

- The management of acute OE should include an assessment of pain. The clinician should recommend analgesic treatment based on the severity of pain.⁴ **SOR B**
- Topical treatments alone are effective for uncomplicated acute OE. Additional oral antibiotics are not required.³ **SOR B**
- The evidence for steroid-only drops is very limited.³ **SOR B**
- Given that most topical treatments are equally effective, it would appear that in most cases the preferred choice of topical treatment may be determined by other factors, such as risk of ototoxicity, risk of contact sensitivity, risk of developing resistance, availability, cost, and dosing schedule.³ **SOR B**

FIGURE 27-5 Acute otitis externa showing purulent discharge and narrowing of the ear canal. (Courtesy of Roy F. Sullivan, PhD. *Audiology Forum: Video Otoscopy*, www.rcsullivan.com.)

FIGURE 27-6 Acute otitis externa in an older man who wears a hearing aid. Note the viscous purulent discharge and narrowing of the ear canal. (Courtesy of Roy F. Sullivan, PhD. *Audiology Forum: Video Otoscopy*, www.rcsullivan.com.)

- Evidence from one trial of low quality found no difference in clinical efficacy between quinolone and nonquinolone drops. Quinolones are more expensive than nonquinolones.³ **SOR B**
- There is some evidence indicating that patients treated with topical preparations containing antibiotics and steroids benefit from reduced swelling, severe redness, secretion, and analgesic consumption compared to preparations without steroids. There is a suggestion that high-potency steroids may be more effective than low-potency steroids (in terms of severe pain, inflammation, and swelling).³ **SOR B**
- Acetic acid was effective and comparable to antibiotic/steroid at week 1. However, when treatment needed to be extended beyond this point it was less effective. In addition, patient symptoms lasted 2 days longer in the acetic acid group compared to antibiotic/steroid group.³ **SOR B**
- Topical aluminum acetate may be as effective as a topical antibiotic/steroid at improving cure rates in people with acute OE.¹ **SOR B**
- Patients prescribed antibiotic/steroid drops can expect their symptoms to last for approximately 6 days after treatment has begun. Although patients are usually treated with topical medication for 7 to 10 days, it is apparent that this will undertreat some patients and overtreat others. It may be more useful when prescribing ear drops to instruct patients to use them for at least a week. If they have symptoms beyond the first week they should continue the drops until their symptoms resolve (and possibly for a few days after), for a maximum of an additional 7 days.³ **SOR B**
- Evidence from one low-quality trial suggests a glycerine-ichthammol medicated wick may provide better pain relief in early severe acute OE than a triamcinolone/gramicidin/neomycin/nystatin medicated wick.³ **SOR B**
- There is no evidence on the use of topical antifungal agents (with or without steroids) in OE.¹ **SOR B**

PREVENTION

- Prophylactic treatments to prevent OE (topical acetic acid, topical corticosteroids, or water exclusion) have not been evaluated in clinical trials.¹ **SOR B**

PROGNOSIS

- Acute OE often resolves within 6 weeks but can recur.

FOLLOW-UP

- If the patient fails to respond to empiric therapy within 48 to 72 hours, the clinician should reassess the patient to confirm the diagnosis of OE and to exclude other causes of illness.⁴ **SOR B**
- Patients with persisting symptoms beyond 2 weeks should be considered treatment failures and alternative management initiated.³ **SOR B**

FIGURE 27-7 Chronic otitis externa in an older woman who wears a hearing aid. The ear canal is not narrowed but is coated with a purulent discharge. (Courtesy of Roy F. Sullivan, PhD. *Audiology Forum: Video Otoscopy*, www.rcsullivan.com.)

PATIENT EDUCATION

- To avoid recurrent infections:⁵
 - Recommend that patients not use cotton swabs inserted into the ear canal.
 - Avoid frequent washing of the ears with soap as this leaves an alkali residue that neutralizes the normal acidic pH of the ear canal.
 - Avoid swimming in polluted waters.
 - Ensure that the canals are emptied of water after swimming or bathing—This can be done by turning the head or holding a facial tissue on the outside of the ear to act as a wick.
- Consider ear drops for swimmers who get frequent OE. A combination of a 2:1 ratio of 70% isopropyl alcohol and acetic acid may be used after each episode of swimming to assist in drying and acidifying the ear canal.⁵ **SOR** 
- Do not use earplugs while swimming because they may cause trauma to the ear canal leading to OE.⁵

28 EAR: FOREIGN BODY

Brian Z. Rayala, MD

PATIENT STORY

A 3-year-old girl is brought by her parents to an urgent care facility after a day of crying, irritability, scant otorrhea, and frequent pulling of her right ear. Otoscopy reveals an erythematous, swollen external auditory canal (EAC) where a bead is wedged (**Figure 28-1**). The patient is referred to an otolaryngologist and the bead is removed using an operating microscope for visualization.

INTRODUCTION

- Children with ear foreign bodies (FBs) usually present with otalgia, otorrhea, or decreased hearing. At times, symptoms may be non-specific, like irritability and crying. Other times, presentation may be asymptomatic.

EPIDEMIOLOGY

- Ear FBs are commonly seen in children ages 1 to 6 years.¹⁻³
- Equal male-to-female ratio in the pediatric population.⁴

ETIOLOGY AND PATHOPHYSIOLOGY

- Most common FBs in children include:⁵
 - Inanimate objects such as beads (see **Figure 28-1**), cotton tips, paper, toy parts, crayons (**Figure 28-2**), eraser tips, food, or organic matter, including sand (**Figure 28-3**), sticks, and stones.
 - Insects (**Figure 28-4**).
- Pathogenesis includes some of the key elements of otitis externa (see Chapter 27, Otitis Externa):
 - Initial breakdown of the skin-cerumen barrier (caused by presence of FB).
 - Skin inflammation and edema leading to subsequent obstruction of adnexal structures (e.g., cerumen glands, sebaceous glands, and hair follicles).
 - FB reaction leading to further skin injury.
 - In the case of alkaline battery electrochemical reaction, severe alkaline burns may occur.

RISK FACTORS

- Children with attention deficit hyperactivity disorder (ADHD) may be more likely to self-insert FBs and ADHD should be considered in children with ear FBs who are older than age 5 years.⁶

FIGURE 28-1 Foreign body (bead) in the ear canal of a 3-year-old girl with reactive tissue around it. (Courtesy of William Clark, MD.)

FIGURE 28-2 Piece of a crayon in the ear canal of a 4-year-old boy. (Courtesy of William Clark, MD.)

DIAGNOSIS

CLINICAL FEATURES

- Key historical features include:
 - Ootalgia.
 - Otorrhea or otorrhagia.
 - Mild hearing loss.
 - Irritability, crying.
 - History suspicious for FB insertion or witnessed FB insertion.
- Some children may be asymptomatic.
- Hallmark of diagnosis includes visualization of FB on otoscopy (see **Figures 28-1** through **28-4**).
- Otoscopy may reveal signs of EAC inflammation (e.g., edema, erythema, aural discharge) (see **Figure 28-1**).

LABORATORY AND IMAGING

- Aural FB is a clinical diagnosis. Laboratory and imaging studies have very limited use.

DIFFERENTIAL DIAGNOSIS

- Otitis externa—Presents with otalgia, otorrhea, and mild hearing loss, all of which can be present in ear FB. Absence of FB (on otoscopic exam) is the key differentiating factor (see Chapter 27, Otitis Externa).
- Acute otitis media (with or without perforated tympanic membrane [TM])—Otoscopy shows absence of FB and presence of middle-ear inflammation and effusion (i.e., bulging, erythematous, cloudy, immobile TM). Patients present with clinical signs or symptoms of acute illness like fever (see Chapter 26, Otitis Media: Acute Otitis and Otitis Media with Effusion).
- Chronic Suppurative Otitis Media—Otoscopy shows absence of FB and presence of TM perforation; history reveals a chronically draining ear and recurrent middle-ear infections with or without hearing loss.

MANAGEMENT

PROCEDURES

- Adequate immobilization of the child (sedation if necessary) and proper instrumentation allow the uncomplicated removal of many ear FBs in the pediatric population.⁷ **SOR C**
 - The use of general anesthesia is preferred in very young children and in children of any age with ear FBs whose contour, composition, or location predispose to traumatic removal in the ambulatory setting.⁷ **SOR C**
- Ear FBs can be removed by irrigation, suction, or instrumentation. The type of procedure depends on the type of FB being removed.
 - Small inorganic objects can be removed from the EAC by irrigation. Contraindication to irrigation includes:
 - Perforated TM.
 - Vegetable matter—Irrigation causes swelling of the vegetable matter which leads to further obstruction.

FIGURE 28-3 Beach sand granules with exostosis in the ear of a cold water surfer. The exostoses are common in cold water swimmers and surfers. (Courtesy of Roy F. Sullivan, PhD. *Audiology Forum: Video Otoscopy*, www.rcsullivan.com.)

FIGURE 28-4 Ant in the ear canal. (Courtesy of Vladimir Zlinsky, MD in Roy F. Sullivan, PhD. *Audiology Forum: Video Otoscopy*, www.rcsullivan.com.)

- Alkaline (button) battery—Irrigation enhances leakage and potential for liquefaction necrosis and severe alkaline burns.
- Objects with protruding surfaces or irregular edges may be removed with alligator forceps under direct visualization.
- Objects that are round or breakable can be removed using a wire loop, a curette, or a right-angle hook that is slowly advanced beyond the object and carefully withdrawn.
- Cyanoacrylate adhesive (e.g., “superglue”) has been used to remove tightly wedged, smooth, round FBs.
- Live insects should be killed before removing them (by irrigation or forceps). Instilling alcohol or mineral oil into the auditory canal can kill them.

REFERRAL

Referral to otolaryngology should be considered if:

- More than one attempt has been carried out without success.⁸
- More than one instrument is needed for removal.⁷
- Patients who have firm, rounded FBs (see **Figure 28-1**).⁹
- Patients who have FBs with smooth, nongrasable surfaces (see **Figure 28-1**).¹⁰

PREVENTION

- Efforts should focus on preventing small children from having access to tiny objects (e.g., beads, small toys, etc.).

PROGNOSIS

- Several retrospective studies from urban emergency departments showed that emergency physicians successfully removed most FBs (53% to 80%) with minimal complications and no need for operative removal.^{7,8-10}

FOLLOW-UP

- Follow-up is very important, especially in cases where EAC inflammation or infection is likely (e.g., numerous attempts, use of numerous instruments, protracted exposure to the FB).

PATIENT EDUCATION

- Parents should be informed that successful removal depends a great deal on the length of time the FB has remained in the EAC.

29 CHONDRODERMATITIS NODULARIS HELICIS AND PREAURICULAR TAGS

Linda French, MD

PATIENT STORY

A 44-year-old white man presents with a painful nodule on his right ear for 1 year (**Figure 29-1**). He has a long history of occupational sun exposure but no skin cancers. He states that it is too painful to sleep on his right side because of the ear nodule. He tried to remove it once with nail clippers but it bled too much. The patient is told that this is likely a benign condition called chondrodermatitis nodularis helicis. A shave biopsy/removal is performed for diagnostic and therapeutic purposes. It is explained to the patient that this could be a skin cancer as a result of his sun exposure history. The biopsy confirms chondrodermatitis nodularis helicis and he is counseled to use sun protection.

INTRODUCTION

Chondrodermatitis nodularis helicis is a benign neoplasm of the ear cartilage commonly believed to be related to excessive pressure, for example, during sleep, and sun exposure. The result is a localized overgrowth of cartilage, and subsequent skin changes. Preauricular tags are malformations of the external ear.

SYNONYMS

Chondrodermatitis nodularis chronica helicis.

EPIDEMIOLOGY

CHONDRODERMATITIS NODULARIS

- The incidence of chondrodermatitis nodularis has not been determined.
- Occurs most commonly in men older than 40 years of age, but older women can also be affected.

PREAURICULAR TAGS

- Occur in approximately 1 of 10,000 to 12,500 births without predilection for gender or race.
- Ear malformations may occur in isolation or as part of a constellation of abnormalities, often involving the renal system. Children have a 5-fold risk of hearing impairment (8 of 10,000 vs. 1.5 of 10,000).¹
- Several chromosomal abnormalities include preauricular tags as one of the phenotypic expressions.
- The Goldenhar syndrome includes preauricular skin tags, bilateral limbal dermoids of the eye and eyelid colobomas (**Figure 29-2**).

FIGURE 29-1 Chondrodermatitis nodularis helicis on the right ear of a 44-year-old man. (Courtesy of Richard P. Usatine, MD.)

FIGURE 29-2 Chondrodermatitis nodularis on the helix of the right ear in a 62-year-old man. Note the pearly appearance, which may be seen with a basal cell carcinoma. (Courtesy of Richard P. Usatine, MD.)

ETIOLOGY AND PATHOPHYSIOLOGY

CHONDRODERMATITIS NODULARIS HELICIS

- In rare cases, especially when occurring at younger ages, the lesion may be related to an underlying disease associated with microvascular injury, such as vasculitis or other necrobiotic collagen disease.²

PREAURICULAR TAGS

- Arise from remnants of supernumerary brachial hillocks.³
- Early stage embryology involves the formation of several slit-like structures on the side of the head, the branchial clefts. The three hillocks between the first four clefts eventually form the structure of the outer ear. Preauricular tags are generally minor malformations arising from remnants of supernumerary branchial hillocks.⁴

DIAGNOSIS

CLINICAL FEATURES OF CHONDRODERMATITIS

- Firm, painful nodule 3-20 mm in size (**Figures 29-1 to 29-4**).
- The helix is most often affected especially in men (**Figures 29-1 and 29-2**). The antihelix is affected more often in women (**Figures 29-3 and 29-4**).
- Overlying skin normal in color or erythematous; a central ulcer may be present.

CLINICAL FEATURES OF PREAURICULAR TAGS

- Fleishy knob in front of the ear (**Figures 29-5 and 29-6**).
- Present from the time of birth.
- Generally asymptomatic.

TYPICAL DISTRIBUTION

- Chondrodermatitis is located at the helix or antihelix of the ear. The right ear is more often affected than the left.
- Preauricular tags may be unilateral or bilateral, more often present on the left.

BIOPSY

- Often required for chondrodermatitis nodularis to rule out malignancy, especially when occurring in individuals with actinic damage and/or history of other skin cancers.
- Not indicated for preauricular tag.

DIFFERENTIAL DIAGNOSIS

- Chondrodermatitis nodularis helicis may be confused with skin cancer, especially squamous cell carcinoma (SCC; see Chapter 171, Squamous Cell Carcinoma). In SCC, the overlying skin is often ulcerated and the tumor has poorly defined margins.
- The key issue in diagnosis of preauricular tags is whether the ear tags are an isolated anomaly or part of a syndrome involving vital

FIGURE 29-3 Chondrodermatitis nodularis on the antihelix of the right ear of an 86-year-old woman. Note the erythema and scale. A shave biopsy was performed to make sure this was not a squamous cell carcinoma. (Courtesy of Richard P. Usatine, MD.)

FIGURE 29-4 Chondrodermatitis nodularis on the antihelix of the right ear of a 52-year-old woman. Note the pearly nodule with central scale. A shave biopsy was performed to rule out basal cell carcinoma and squamous cell carcinoma. (Courtesy of Richard P. Usatine, MD.)

organs, especially the kidneys. There is no consensus about whether children with ear tags who otherwise appear to be healthy should be evaluated with renal ultrasound.^{4,5}

MANAGEMENT

Chondrodermatitis nodularis is treated with the following:

NONPHARMACOLOGICAL

- A pressure-relieving prosthesis or donut-shaped pillow can be used.^{6,7} **SOR C** This can also be created by cutting a hole from the center of a bath sponge. The sponge can then be held in place with a headband if needed. A special prefabricated pillow is available from <http://www.cnhpillow.com/>.

PROCEDURES

- Shave biopsy can be used to make the diagnosis and may relieve symptoms temporarily. **SOR C**
- Cryotherapy, intralesional steroids, or curettage and electrodesiccation can be performed after the result from the shave biopsy is known and there is no malignancy. **SOR C**
- Photodynamic therapy (combines a photosensitizer with a specific type of light to kill nearby cells) has been reported to decrease pain in case reports.⁸ **SOR C**
- A small elliptical excision of the nodule with removal of inflamed cartilage provides excellent results (**Figure 29-7**).^{9,10} **SOR C**
- Preauricular tags can be left alone or surgically excised for cosmetic reasons. **SOR C**

FOLLOW-UP FOR CHONDRODERMATITIS NODULARIS

- Recurrences are common and may require further treatment.

PATIENT EDUCATION

- Chondrodermatitis nodularis is a benign lesion that tends to recur; therapeutic options can be discussed.
- There is a low risk of urinary tract abnormalities in children who have apparently isolated preauricular tags and an increased risk of hearing impairment.

PATIENT RESOURCES

- A special prefabricated pillow is available that helps relieve pressure on the ear. For more information, contact: CNH Pillow, PO Box 1247, Abilene, TX 79604; phone (800) 255-7487; <http://www.cnhpillow.com/>.
- Preauricular tags—<http://nlm.nih.gov/medlineplus/ency/article/003304.htm>.

SECTION 2 NOSE AND SINUS

30 NASAL POLYPS

Linda French, MD

PATIENT STORY

A 35-year-old man complains of unilateral nasal obstruction for the past several months of gradual onset. On examination of the nose, a nasal polyp is found (**Figure 30-1**).

INTRODUCTION

Nasal polyps are benign lesions arising from the mucosa of the nasal passages including the paranasal sinuses. They are most commonly semitransparent.

EPIDEMIOLOGY¹

- Prevalence of 1% to 4% of adults; 0.1% of children of all races and classes.
- The male-to-female ratio in adults is approximately 2:1.
- Peak age of onset is 20 to 40 years old; rare in children younger than 10 years old.
- Associated with the following conditions:
 - Nonallergic and allergic rhinitis and rhinosinusitis.
 - Asthma—In 20% to 50% of patients with polyps.
 - Cystic fibrosis.
 - Aspirin intolerance—In 8% to 26% of patients with polyps.
 - Alcohol intolerance—In 50% of patients with polyps.

ETIOLOGY AND PATHOPHYSIOLOGY

- The precise cause of nasal polyp formation is unknown.
- Infectious agents causing desquamation of the mucous membrane may play a triggering role.
- Activated epithelial cells appear to be the major source of mediators that induce an influx of inflammatory cells, including eosinophils prominently; these in turn lead to proliferation and activation of fibroblasts.² Cytokines and growth factors play a role in maintaining the mucosal inflammation associated with polyps.
- Food allergies are strongly associated with nasal polyps.

FIGURE 30-1 Nasal polyp in left middle meatus with normal surrounding mucosa. (Courtesy of William Clark, MD.)

DIAGNOSIS

CLINICAL FEATURES

- The appearance is usually smooth and rounded (**Figure 30-1**).
- Moist and translucent (**Figure 30-2**).
- Variable size.
- Color ranging from nearly none to deep erythema.

TYPICAL DISTRIBUTION

- The middle meatus is the most common location.

LABORATORY AND IMAGING

- Consider allergy testing.
- In children with multiple polyps, order sweat test to rule out cystic fibrosis.
- CT of the nose and paranasal sinuses may be indicated to evaluate extent of lesion(s) (**Figure 30-3**).

BIOPSY

- Not usually indicated. Histology typically shows pseudostratified ciliary epithelium, edematous stroma, epithelial basement membrane, and proinflammatory cells with eosinophils present in 80% to 90% of cases.

DIFFERENTIAL DIAGNOSIS

Many relatively rare conditions can cause an intranasal mass including (in adults):

- Papilloma—About 1% of nasal tumors, affecting 1 in 100,000 adults per year. Locally invasive, these tend to recur especially if excision is not complete. Papillomas are of unknown etiology but are associated with chronic sinusitis, air pollution, and viral infections. They are irregular and friable in appearance and bleed easily.³
- Meningoencephalocele—Grayish gelatinous appearance.⁴
- Nasopharyngeal carcinoma—Firm, often ulcerated.
- Pyogenic granuloma—Relatively common benign vascular neoplasm of skin and mucous membranes (see Chapter 161, Pyogenic Granuloma).⁵
- Chordoma—Locally invasive neoplasms with gelatinous appearance that arise from notochordal (embryonic) remnants. Occurs in all age groups (mean age: 48 years).⁶
- Glioblastoma—Rare manifestation of the most common kind of brain tumor in adults.

Conditions that may mimic nasal polyp in children include:

- Rhabdomyosarcoma—Malignant tumor of childhood originating from striated muscle.
- Dermoid tumor—Inclusion cysts of ectodermal epithelial elements, usually manifest before 20 years of age. May grow slowly.
- Hemangioma—Congenital, abnormal proliferation of blood vessels that may occur in any vascularized tissue (see Chapter 109, Childhood Hemangiomas and Vascular Malformations).

FIGURE 30-2 Nasal polyp in right nasal cavity in a patient with inflamed mucosa from allergic rhinitis. (Courtesy of William Clark, MD.)

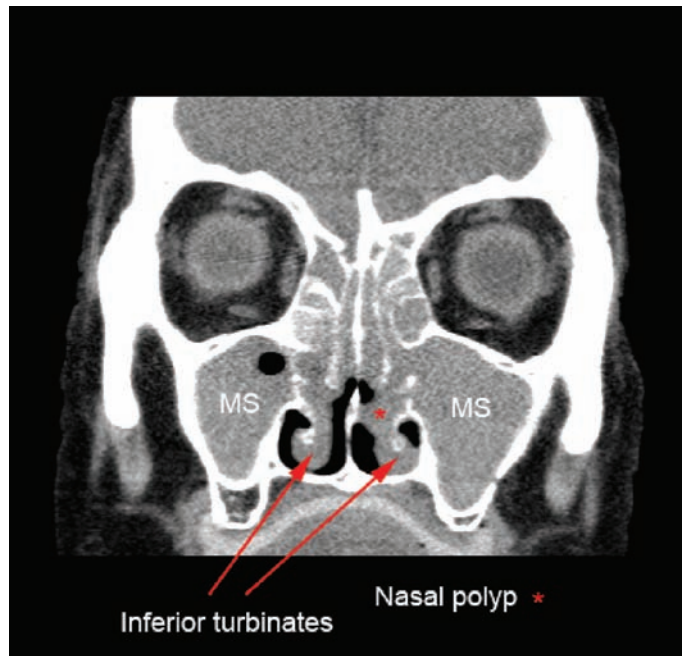

FIGURE 30-3 CT scan showing polyps (asterisk) and bilateral opacified maxillary sinuses (MS). Note the nasal polyp appears to be coming from the left maxillary sinus and is above the inferior turbinate. (Courtesy of Richard P. Usatine, MD.)

- Neuroblastoma—Unusual presentation of relatively common malignancy of childhood.
- Meningoencephalocele—Grayish gelatinous appearance.
- Angiofibroma—Locally invasive neoplasm that appears as a firm grayish mass. Bleeds easily. Occurs in adolescent males ages 14 to 18 years. Undetermined etiology.⁷
- Pyogenic granuloma (see Chapter 161, Pyogenic Granuloma).⁵

MANAGEMENT

MEDICATIONS

- Medical treatment consists of intranasal corticosteroids.⁸ **SOR A**
- An initial short course (2 to 4 weeks) of oral steroids may be considered in severe cases.^{9,10} **SOR A**
- Steroid treatment reduces polyp size, but does not generally resolve them. Corticosteroid treatment is also useful preoperatively to reduce polyp size.
- Oral doxycycline 100 mg daily for 20 days was shown to decrease polyp size, providing benefit for 12 weeks in one randomized controlled trial.¹¹ **SOR B**
- Topical nasal decongestants may provide some symptom relief, but do not reduce polyp size.¹² **SOR B**
- Montelukast reduces symptoms when used as an adjunct to oral and inhaled steroid therapy in patients with bilateral nasal polyposis.¹³ **SOR B**

PROCEDURES

- Surgical excision is often required to relieve symptoms.
- Consider immunotherapy for patients with allergies.

PROGNOSIS

Lesions are benign and tend to recur.

FOLLOW-UP

- Periodic reevaluation is recommended because recurrence rates are high.¹⁴

PATIENT EDUCATION

- Patients should be informed about the benign nature of nasal polyps and their tendency to recur.

31 SINUSITIS

Mindy A. Smith, MD, MS

PATIENT STORY

A 55-year-old woman complains of sinus pressure for the past 2 weeks along with headache, rhinorrhea, postnasal drip, and cough. This all started with a cold 3 weeks ago. She has chronic allergic rhinitis, but now the pressure on the right side of her face has become intense and her right upper molars are painful. The nasal discharge has become discolored and she feels feverish. She is diagnosed clinically with right maxillary sinusitis and is prescribed an antibiotic. Two weeks later when her symptoms have persisted, a CT is ordered and she is found to have air-fluid levels in both maxillary sinuses and loculated fluid on the right side. (**Figures 31-1** and **31-2**.) The antibiotic is changed to amoxicillin/clavulanate and she is given information about nasal saline irrigation for symptom relief. If the symptoms don't improve the clinician plans to send her to ENT for further evaluation.

INTRODUCTION

Rhinosinusitis is symptomatic inflammation of the sinuses, nasal cavity, and their epithelial lining.¹ Mucosal edema blocks mucous drainage, creating a culture medium for viruses and bacteria. Rhinosinusitis is classified by duration as acute (<4 weeks), subacute (4 to 12 weeks), or chronic (>12 weeks).

EPIDEMIOLOGY

- Rhinosinusitis is common in the United States, with an estimated prevalence of 14% to 16% of the adult population annually.^{1,2} The prevalence is increased in women and in individuals living in the southern United States.
- Only one-third to one-half of primary care patients with symptoms of sinusitis actually have bacterial infection.³
- Sinusitis is the fifth-leading diagnosis for which antibiotics are prescribed in the United States.¹
- Children average 6 to 8 colds per year. Of those, 0.5% to 8% will develop a sinus infection.^{4,5}
- This problem is responsible for millions of office visits to primary care physicians each year.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- Sinus cavities are lined with mucous-secreting respiratory epithelium. The mucus is transported by ciliary action through the sinus ostia (openings) to the nasal cavity. Under normal conditions, the paranasal sinuses are sterile cavities and there is no mucous retention.

FIGURE 31-1 Bilateral maxillary sinusitis on axial CT. Note that fluid levels are greater on the right. (Courtesy of Chris McMains, MD.)

FIGURE 31-2 Maxillary sinusitis on coronal CT of same patient. (Courtesy of Chris McMains, MD.)

- Bacterial sinusitis occurs when ostia become obstructed or ciliary action is impaired, causing mucus accumulation and secondary bacterial overgrowth.
- The causes of sinusitis include:⁶
 - Infection – most commonly viral (e.g., rhinovirus, parainfluenza, and influenza) followed by bacteria infection (e.g., community-acquired acute cases – about half from *S. pneumoniae* and *Haemophilus influenzae* followed by *Moraxella catarrhalis*). In immunocompromised patients, fulminant fungal sinusitis may occur (e.g., rhinocerebral mucormycosis – **Figure 31-3**).
 - Noninfectious obstruction—Allergic, polyposis, barotrauma (e.g., deep-sea diving, airplane travel), chemical irritants, tumors (e.g., squamous cell carcinoma, granulomatous disease, inverting papilloma), and conditions that alter mucous composition (e.g., cystic fibrosis).

DIAGNOSIS

The diagnosis is based on the clinical picture with typical symptoms listed below. Symptoms arising from viral infection generally peak by day 5 or before. Acute bacterial rhinosinusitis is diagnosed when symptoms are present for 10 days or longer or when symptoms worsen after initial stability or improvement (“double worsening” or “double sickening”); it can also be presumed in patients with unusually severe presentations or extrasinus manifestations of infection.¹ Superimposed bacterial infection is estimated to occur in 0.5% to 2% of cases of viral rhinosinusitis.¹

CLINICAL FEATURES

- Most cases are seen in conjunction with viral upper respiratory infections and represent sinus inflammation rather than infection.³
- Nonspecific symptoms include cough, sneezing, fever, nasal discharge (may be purulent or discolored), congestion, and headache.
- The American Academy of Otolaryngology guideline and the European Position Paper on Rhinosinusitis and Nasal Polyps recommend a diagnosis of rhinosinusitis with a combination (2 or more) of purulent nasal drainage associated with nasal obstruction, facial pain-pressure-fullness, or both; the latter also recognizes reduction/loss of smell as a cardinal feature.^{1,7} There are no prospective trials that validate this approach.
- Other localizing symptoms include facial pain or pressure over the involved sinus when bending over or supine (i.e., forehead in frontal sinusitis, cheek with maxillary sinusitis, between the eyes with ethmoid sinusitis, and neck and top of the head with sphenoid sinusitis) and maxillary tooth pain, most commonly the upper molars; the latter is seen more often with bacterial sinusitis. Halitosis is also attributed to bacterial causes.
- In a study of patients with chronic rhinosinusitis, diagnosis based on symptoms was problematic and only dysosmia (impairment in the sense of smell) and the presence of polyps could distinguish between normal and abnormal radiographs.⁸

TYPICAL DISTRIBUTION

- Most sinus infections involve the maxillary sinus followed in frequency by the ethmoid (anterior), frontal, and sphenoid sinuses; however, most cases involve more than one sinus.⁵

FIGURE 31-3 Mucormycosis sinusitis in a patient with diabetes showing the classic black nasal discharge. (Courtesy of Randal A. Otto, MD.)

- Children are more likely to have inflammation in the posterior ethmoid and sphenoid sinuses.⁹

LABORATORY AND IMAGING

- Culture of nasal or nasopharyngeal secretions is not recommended as these have not been shown to differentiate between bacterial and viral rhinosinusitis.¹
- If culture is needed because of suspected bacterial resistance or persistence of infection, a recent metaanalysis found endoscopically directed middle meatal cultures to be reasonably sensitive (80.9%), specific (90.5%), and accurate (87.0%; 95% confidence interval, 81.3% to 92.8%) compared with maxillary sinus taps.¹⁰
- Radiography should not be obtained for patients meeting diagnostic criteria for acute rhinosinusitis, unless a complication or alternate diagnosis is suspected.¹ If performed in cases of clinical uncertainty or for complications (e.g., orbital, intracranial, or soft-tissue involvement), plain sinus radiography is considered positive for acute sinusitis with the presence of air-fluid level, complete opacification, or at least 6 mm of mucosal thickening; it has a reported sensitivity of 76% and specificity 79%.¹¹ There are considerable limitations to the sensitivity of plain films, especially in diagnosing ethmoid and sphenoid disease.
- For children, ultrasound compared favorably to plain film for suspected maxillary sinusitis (94.9% sensitivity, 98.4% specificity).¹²
- Nasal endoscopy, identifying purulent material within the drainage area of the sinuses, may be comparable to plain sinus radiography in diagnosing acute sinusitis.¹⁰ In one case series of patients with suspected chronic rhinosinusitis, the addition of endoscopy to symptom criteria had similar sensitivity (88.7% vs. 84.1%) but significantly improved specificity (66% vs. 12.3%) using CT as the gold standard.¹³
- In acute disease, CT scanning is generally reserved for persistent or recurrent symptoms to confirm sinusitis, or to investigate infectious complications (Figures 31-4 and 31-5). Radiation dose (about 10 times that of plain radiography) can be lowered with careful choice of technical factors.¹

REFER OR HOSPITALIZE

- Potentially life threatening complications include subperiosteal orbital abscess, meningitis, epidural or cerebral abscess, and cavernous sinus thrombosis (Figures 31-6 and 31-7).
- The risks of frontal sinusitis includes eroding through the frontal bone forward and causing a Pott's puffy tumor, inward and spreading into the brain and cavernous sinuses (Figure 31-5).
- Orbital abscess is highly dangerous and can be the result of spread from the frontal or ethmoid sinuses (Figure 31-6).
- In immunocompromised patients, fulminant fungal sinusitis may cause orbital swelling, cellulitis, proptosis, ptosis, impairment of extra-ocular motion, nasopharyngeal ulceration, and epistaxis. Bony erosion may be evident.⁷ Nasal mucosa may appear black (Figure 31-3), blanched white, or erythematous.
- In hospitalized patients, patients may be critically ill and without localizing symptoms. Infections in these patients are often polymicrobial including *S. aureus*, *Pseudomonas aeruginosa*, *Serratia marcescens*, *Klebsiella pneumoniae*, and *Enterobacter*.⁷

FIGURE 31-4 Mucopycele in the sphenoid sinus (arrow) as a complication of bacterial sinusitis. (Courtesy of Randal A. Otto, MD.)

FIGURE 31-5 Frontal sinusitis eroded through the frontal bone inward toward the brain threatening such complications as a brain abscess and cavernous sinus thrombosis. Seen on CT scan. (Courtesy of Randal A. Otto, MD.)

DIFFERENTIAL DIAGNOSIS

- Upper respiratory tract infections—These are common infections, primarily viral (most commonly rhinovirus), that cause 2 to 4 infections per year in adults and 6 to 8 infections per year in children. Infections are self-limited (lasting approximately 7 to 10 days) and typical symptoms include rhinorrhea, nasal congestion, sore throat, and cough. Upper respiratory infection (URI) often precedes acute sinusitis.
- Allergic rhinitis—Sneezing, itching, watery rhinorrhea.
- Tumor (usually squamous cell carcinoma)—Rare; unilateral epistaxis or discharge and obstruction, recurrent sinusitis, sinus pain.

Other causes of facial pain include:

- Migraine headache or cluster headache—Moderate to severe head pain that is usually deep seated, persistent, and pulsatile. There is a history of multiple occurrences and head pain may be associated with nausea, vomiting, photophobia, and scotomata. Attacks last 4 to 72 hours.
- Trigeminal neuralgia—Painful condition characterized by excruciating, paroxysmal, shock-like pain lasting seconds to minutes along the distribution of the trigeminal nerve (ophthalmic, maxillary and/or mandibular branches). Pain may be triggered by face washing, air draft, and chewing.
- Dental pain—Tooth pain may be secondary to caries or gingivitis. When caries extend into the tooth pulp, the tooth becomes sensitive to percussion and hot and cold food and beverages. If pulp necrosis occurs, pain becomes severe, sharp, throbbing, and often worse when supine. Abscess formation results in pain, swelling and erythema of the gum and surrounding tissue, and possibly purulent drainage.
- Temporal arteritis—Unilateral pounding headache that may be associated with visual changes and systemic symptoms (e.g., fever, weight loss, muscle aches). Onset is usually older adults (older than age 50 years) and laboratory testing reveals an elevated erythrocyte sedimentation rate (>50).

MANAGEMENT

Duration of illness assists in decision making as most patients improve without specific treatment; a period of watchful waiting for up to 7 days is consistent with guidelines.¹ Treatment of symptoms, including pain, is important.

NONPHARMACOLOGIC

- Nasal saline irrigation for acute upper respiratory tract infection in adults is generally not helpful, although data are limited¹⁴; two trials suggested modest benefit from buffered hypertonic (3% to 5%) saline irrigation for acute rhinosinusitis.¹ **SOR B** In adults with chronic sinusitis, nasal saline irrigation provides symptom relief, both alone and as an adjunct to nasal steroids, and is well tolerated.¹⁵ **SOR B**

MEDICATIONS

- Analgesics (acetaminophen or nonsteroidal antiinflammatory drugs alone or in combination with an opioid) should be used for pain.¹
- Oral and topical (nasal) decongestants may be offered for symptomatic relief; however, there are no randomized controlled trials

FIGURE 31-6 Right orbital abscess with proptosis as a complication of frontal sinusitis eroding through the superior orbital bones. (Courtesy of Randal A. Otto, MD.)

FIGURE 31-7 Mucopyocele (red arrow) in the right frontal sinus seen on MRI scan as a complication of frontal sinusitis. (Courtesy of Randal A. Otto, MD.)

(RCTs) demonstrating effectiveness for sinusitis and the effect is limited to the nasal cavity.¹⁶ Topical agents are more potent but rebound nasal congestion may develop after discontinuation; use for 3 days only is suggested.¹

- Topical corticosteroids appear to be of benefit in improvement and resolution of symptoms for acute sinusitis.¹⁷ **SOR B**
- There have been no clinical trials of mucolytics reported in nonatopic children or adults with acute bacterial sinusitis. However, they may be useful in preventing crust formation and liquefying secretions. **SOR C**
- Patients who fail to improve or have severe symptoms may be offered oral antibiotics. **SOR A** Although 10 days is usually recommended for adults, a shorter course (3 to 5 days) may be equally effective.¹
 - Adults (after 7 days)—Amoxicillin (500 mg three times daily or 875 mg twice daily) for 10 days¹; alternatives include trimethoprim-sulfamethoxazole (TMS-SMX) (1 DS twice daily) or a macrolide for 10 days.¹
 - Children (after 10 to 14 days of symptoms)—Amoxicillin (45 to 90 mg/kg divided twice daily), cefuroxime axetil (30 mg/kg divided twice daily), or cefdinir (14 mg/kg daily) for 10 to 14 days.^{4,6,18}
- In a Cochrane review of 59 trials evaluating antibiotic treatment for acute maxillary sinusitis, antibiotics decreased clinical failure by approximately 10%.¹⁹ Comparisons between classes of antibiotics showed no significant differences; therefore, narrow-spectrum antibiotics should be first-line therapy.¹⁹
- Based on the Otolaryngology Head and Neck Surgery clinical guideline, the modest benefit of antibiotics for improving rates of clinical cure or improvement at 7 to 12 days (number needed to treat = 7) must be weighed against the risks of harm (primarily gastrointestinal, but also skin rash, vaginal discharge, headache, dizziness, and fatigue [number needed to harm = 9]).¹

PROCEDURES

- Surgery and intravenous antibiotics are used for complications, including abscess and cases with orbital involvement.⁶
- Patients with fungal sinusitis are treated with aggressive debridement and adjunctive antifungals (e.g., amphotericin).⁶
- Based on three RCTs, endoscopic sinus surgery is not superior to medical treatment; in one study there was a lower relapse rate (2.4% vs. 5.6% without surgery).²⁰ **SOR B** Patients should be selected based on the severity of disease (frequency of antibiotics/oral steroid use), comorbidities (asthma, aspirin sensitivity, etc.), and overall clinical picture (presence of polyps or fungal disease).

COMPLEMENTARY AND ALTERNATIVE MEDICINE

- With respect to alternative therapy, there is limited evidence that Sinupret and bromelain may be effective adjunctive treatments in acute rhinosinusitis.²¹ **SOR B**

PREVENTION

- Smoking increases the risk for sinusitis; patients should be counseled about cessation.¹

PROGNOSIS

- Based on a Cochrane review, cure or improvement rate for acute sinusitis within 2 weeks was high in both the placebo group (80%) and the antibiotic group (90%).¹⁹
- For patients with chronic sinusitis, a retrospective study of medical treatment reported treatment success in about half of patients (N = 74); 26 patients had partial resolution and 45 patients underwent surgery. Facial pressure/pain, mucosal inflammation, and higher endoscopic severity grade predicted treatment failure.²²

FOLLOW-UP

- For those adults who fail treatment after 7 days of antibiotic therapy,¹ a nonbacterial cause or resistant organism should be considered; amoxicillin-clavulanate (4 g per day amoxicillin equivalent) twice daily for 10 days, or a respiratory fluoroquinolone (e.g., levofloxacin, 500 mg daily) for 7 days are alternatives.^{1,6} **SOR C**

PATIENT EDUCATION

- Nasal congestion, purulent rhinitis, and facial pain following a cold may indicate a sinus infection. Symptoms due to a cold usually abate within 1 week.
- Methods to improve sinus drainage include oral and nasal decongestants and nasal saline irrigation. Patients should be cautioned against using nasal decongestants for more than three days to avoid rebound symptoms. For longer-term management, topical nasal steroids may prove useful.
- Patients should be encouraged to see their primary care provider if symptoms persist or worsen after 10 days, suggesting bacterial infection that may benefit from antibiotic treatment.

SECTION 3 MOUTH AND THROAT

32 ANGULAR CHEILITIS

Linda French, MD
Richard P. Usatine, MD

PATIENT STORY

A middle-aged woman presents to your office with soreness at the corners of her mouth for 4 months (**Figure 32-1**). On examination, she has cracking and fissures at the right corner of her mouth. She is diagnosed with angular cheilitis and treated with nonprescription nystatin ointment twice daily. Within 2 weeks she was fully healed.

INTRODUCTION

Angular cheilitis is an inflammatory lesion of the commissure or corner of the lip characterized by scaling and fissuring.

SYNONYM

Perlèche, angular cheilosis, commissural cheilitis, angular stomatitis

EPIDEMIOLOGY

- Most common in the elderly. In one study of institutionalized elderly patients in Scotland, angular cheilitis was present in 25% of patients.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- Maceration is the usual predisposing factor. Microorganisms, most often *Candida albicans*, can then invade the macerated area (**Figure 32-2**).²
- It may also occur in infants and children related to drooling, thumb sucking, and lip licking (**Figure 32-3**).
- Lip licking can cause a contact dermatitis to the saliva along with perlèche (**Figure 32-4**). Perlèche is derived from the French word, “lecher,” meaning to lick.
- Historically associated with vitamin B deficiency, which is rare in developed countries.

RISK FACTORS

- Maceration which can be related to poor dentition, deep facial wrinkles, orthodontic treatment, or poorly fitting dentures in the elderly (**Figure 32-5**).

FIGURE 32-1 Angular cheilitis (perlèche). Note dry, erythematous, and fissured appearance. (Courtesy of Richard P. Usatine, MD.)

FIGURE 32-2 *Candida albicans* seen under the microscope after gently scraping a case of angular cheilitis and using KOH on the slide. (Courtesy of Richard P. Usatine, MD.)

- Other risk factors include incorrect use of dental floss causing trauma or diseases that enlarge the lips such as orofacial granulomatosis.
- Atopic dermatitis (**Figure 32-6**).
- HIV or other types of immunodeficiency may lead to more severe case of angular cheilitis with overgrowth of *Candida* (**Figure 32-7**).
- Use of isotretinoin which dries the lips and predisposes to angular cheilitis.

DIAGNOSIS

CLINICAL FEATURES

- Erythema and fissuring at the corners of the mouth, without exudates or ulceration (**Figures 32-3 to 32-7**).

TYPICAL DISTRIBUTION

- Corners of the mouth (oral commissures or angles of the mouth) hence the names commissural cheilitis and angular cheilitis.

LABS

- A light scraping of the corner of the mouth can be placed on a slide with KOH to look for *Candida* (**Figure 32-2**).

BIOPSY

- Not usually indicated.

DIFFERENTIAL DIAGNOSIS

- Impetigo—Yellowish crusts or exudates are characteristic of impetigo but not angular cheilitis (see Chapter 116, Impetigo).
- Herpes simplex (cold sores)—Initial blisters, followed by shallow ulcers, are characteristic of herpes simplex, but not angular cheilitis (see Chapter 129, Herpes Simplex).

MANAGEMENT

NONPHARMACOLOGIC

- Attempt to relieve precipitating causes such as poorly fitting dentures.
- Counsel patients to stop licking their lips if this is part of the cause (**Figure 32-4**).
- Recommend protective petrolatum or lip balm as needed.
- Counsel patients to stop using tobacco, either chewing or smoking.

MEDICATIONS

- Recommend topical antifungal creams or ointments, such as clotrimazole, to be applied twice daily.³ **SOR B**
- Low-potency topical corticosteroid, such as 1% hydrocortisone cream twice daily, may be added to treat the inflammatory component. **SOR B**
- Nystatin lozenges work well but their use is limited because of their unpleasant taste.³ **SOR C** If thrush is also present, prescribe clotrimazole troches for treatment of both conditions.

FIGURE 32-3 Angular cheilitis in a one-year-old girl with widespread atopic dermatitis on her extremities. (Courtesy of Richard P. Usatine, MD.)

FIGURE 32-4 Perlèche in a woman with contact dermatitis related to lip licking. (Courtesy of Richard P. Usatine, MD.)

FIGURE 32-5 Angular cheilitis in an elderly woman. Note the wrinkle line extending downward from the corner of her mouth indicating some change in her facial anatomy that can predispose to this condition. The perlèche started while she was waiting for her dentures to be repaired. (Courtesy of Richard P. Usatine, MD.)

- One randomized controlled study showed that medicated chewing gum can decrease the risk of angular cheilitis in older occupants of nursing homes. Consider recommending xylitol-containing gum to elderly patients with angular cheilitis.⁴ **SOR B**

PREVENTION

Attempt to identify predisposing factors and correct if possible, such as:

- Edentulousness.
- Poorly fitting dentures.
- Drooling.
- Lip licking (**Figure 32-4**)
- Atopic dermatitis (**Figures 32-3 and 32-6**)

Protective lip balm may be helpful to prevent recurrences as long as the patient is not allergic to chemicals within the product. Plain petrolatum is often the safest product for dry lips.

PATIENT EDUCATION

- Encourage patients to identify and correct predisposing factors (as above). Protective lip balm may be helpful.

33 TORUS PALATINUS

Linda French, MD
Mindy A. Smith, MD, MS

PATIENT STORY

An elderly woman is in the office for a physical examination. While looking in her mouth, a torus is seen at the midline on the hard palate (**Figure 33-1**). She states that she has had this for her whole adult life and it does not bother her. You explain to her that it is a torus palatinus and that nothing needs to be done. She is pleased to know the name of this lump and even happier to know that it is not harmful.

INTRODUCTION

Torus palatinus is a benign bony exostosis (bony growth) occurring in the midline of the hard palate. Torus mandibularis often presents as multiple benign bony exostoses on the floor of the mouth.

EPIDEMIOLOGY

- Most common bony maxillofacial exostosis, unclear origin.
- Usually in adults older than 30 years of age.
- Prevalence ranges from 9.5% to 26.9%; among ethnic groups, the range is wider (0.9% in Vietnamese to 33.8% among African Americans).¹
- More common in women than men.
- Some populations seem to be more predisposed (e.g., Middle Eastern).²

DIAGNOSIS

CLINICAL FEATURES

- Hard lump protruding from the hard palate into the mouth covered with normal mucous membrane (**Figure 33-2**).
- Small size (<2 mm) appear most frequent (70% to 91%).¹
- Shapes include flat, nodular, lobular, or spindle-shaped; nodular appear most common.¹

TYPICAL DISTRIBUTION

- Midline hard palate.

DIFFERENTIAL DIAGNOSIS

- Torus mandibularis is also a bony exostosis but is found under the tongue. These appear similar to a torus palatinus but are usually bilateral rather than midline (**Figure 33-2**).

FIGURE 33-1 Torus palatinus in a 66-year-old woman. The patient was asymptomatic and this was an incidental finding. (Courtesy of Richard P. Usatine, MD.)

FIGURE 33-2 Torus mandibularis seen under the tongue caused by bony exostoses. Note these are bilateral and appear similar to a torus palatinus. Although this patient had multiple untreated dental problems, the tori were asymptomatic and this was an incidental finding. (Courtesy of Richard P. Usatine, MD.)

- Squamous cell carcinoma is not as hard and the mucous membranes are usually ulcerated. Mucous membranes are normal in appearance with torus palatinus unless traumatized.
- Adenoid cystic carcinoma is a rare tumor that can start in a minor salivary gland over the hard palate. Note that this tumor will not be midline as found in the torus palatinus. If a suspected torus is not midline a biopsy is needed to rule out this potentially fatal carcinoma (**Figure 33-3**).

MANAGEMENT

- Excision can be considered if the lesion interferes with function, such as the fit of dentures. This is performed as an outpatient procedure.^{3,4}
- Sometimes removed because of disturbances of phonation, traumatic inflammation or ulcer, aesthetic reasons, or as source of autogenous cortical bone for grafts in periodontal surgery.¹

PROGNOSIS

- Very slow growing; can stop growth spontaneously.¹
- Surgical complications include perforation of nasal cavities, palatine nerve damage, bone necrosis, hemorrhage and fracture of palatine bone.¹

PATIENT EDUCATION

- Patients should be informed about the benign nature of the lesion and that removal can be considered, if bothersome.

34 SCARLET FEVER AND STRAWBERRY TONGUE

Mark Jason Sanders, MD
Linda French, MD

PATIENT STORY

A 7-year-old boy is brought to the family physician's office with a rough red rash on his trunk (**Figures 34-1** and **34-2**) along with fever and a sore throat. The sandpaper rash and signs consistent with strep pharyngitis lead the physician to diagnose scarlet fever. The physician explains the diagnosis to the mother and oral Pen VK is prescribed. The boy feels markedly better by the next day, and the mother continues to give the penicillin for the full 10 days as directed to prevent rheumatic fever.

INTRODUCTION

Scarlet fever is an illness caused by toxin-producing group A β -hemolytic streptococci. Most commonly, scarlet fever evolves from an exudative pharyngitis.

Strawberry tongue may be observed in patients with scarlet fever, and usually develops within the first 2 to 3 days of illness. A white or yellowish coating usually precedes the classic red tongue with white papillae (**Figure 34-3**).

EPIDEMIOLOGY

- Scarlet fever is predominately seen in school-age children with no gender predilection.
- Majority related to strep pharyngitis, with 1 in 10 developing scarlet fever (**Figures 34-1**, **34-2**, and **34-4**).
- Prevalent in late fall to early spring.
- Strawberry tongue (**Figure 34-4**) is most commonly seen in children in association with scarlet fever or Kawasaki disease.
- Can be present with other group A *Streptococcus* (strep) infection.
- In cases of strep, a white membrane through which the papillae are seen can initially cover the tongue followed by desquamation of the membrane (with the appearance as in **Figure 34-4**).

ETIOLOGY AND PATHOPHYSIOLOGY

- Transmission of *Streptococcus* occurs via respiratory secretions.
- Virulent *Streptococcus pyogenes* (group A *Streptococcus* or GAS) incubate more than 2 to 7 days. M protein serotypes of GAS are typically more invasive with greater potential for progression to rheumatic fever or acute glomerulonephritis if untreated.¹

FIGURE 34-1 Sandpaper rash on the trunk and in the axilla of a 7-year-old boy with scarlet fever. (Courtesy of Richard P. Usatine, MD.)

FIGURE 34-2 Scarlatiniform rash comprising small papules and erythema on the trunk of a febrile child with strep pharyngitis. (Courtesy of Richard P. Usatine, MD.)

- Fever and rash are related to pyrogenic A–C and erythrogenic exotoxins produced by GAS.²
- Infection may originate from other sites like skin (e.g., cellulitis), and seed blood (bacteremia) or organ systems (e.g., pneumonia).
- Strawberry tongue results from a general inflammatory response during the early course of the disease.

DIAGNOSIS

CLINICAL FEATURES

- Headache, sore throat, cervical lymphadenopathy, abdominal pain, nausea and vomiting, decreased oral intake, malaise, and fever may precede rash. Cough is usually not present.
- Oropharyngeal findings include:
 - Strawberry tongue—Erythematous and sometimes edematous tongue with prominent papillae (**Figure 34-4**).
- May be covered by a white membrane/coating through which the papillae can be seen.
- Not typically painful.
- Forchheimer spots—Palatal and uvular petechiae and erythematous macules.
- Initial sandpaper rash, associated with blanching erythema and occasional pruritus, erupts in 1 to 2 days (**Figures 34-1 to 34-3**).²
- Pastia's lines are pink or red lines seen in the body folds (especially elbows and axilla) during scarlet fever. Linear hyperpigmentation may persist after the rash fades (**Figure 34-1**).
- Desquamation of the skin (especially of the hands and feet) ensues in 3 to 4 days as rash fades and can persist for 2 to 4 weeks.¹

TYPICAL DISTRIBUTION

- Progresses centrally (torso) to peripherally (extremities) and can be prominent on the face, chest, palms, fingers, and toes.¹

LABORATORY TESTS AND IMAGING

- Throat swab for rapid strep testing (screening) and/or culture (confirmation) is usually performed.
- Complete blood count (CBC), if indicated, to look for:
 - Elevation of white blood cell count with left shift.
 - Elevated platelet count—Seen with Kawasaki disease (after 1 week).
- Antistreptolysin-O titer is obtained to confirm prior infection or support suspected poststreptococcal complication, such as rheumatic fever.³
- Acute phase reactants (C-reactive protein [CRP] and erythrocyte sedimentation rate [ESR]) may be elevated, and may be useful in monitoring nonsuppurative complications such as rheumatic fever.⁴
- If Kawasaki disease is suspected, two-dimensional echocardiography or angiography is obtained to detect coronary artery abnormalities. The initial echocardiogram should be performed as soon as the diagnosis is suspected to establish a baseline for longitudinal follow-up of coronary artery morphology, left ventricular and left valvular function, and the evolution and resolution of pericardial effusion when present.⁴ **SOR** **C**

FIGURE 34-3 Sandpaper rash (scarlatiniform) seen prominently on the hand of a child recovering from strep pharyngitis. (Courtesy of Richard P. Usatine, MD.)

FIGURE 34-4 Strawberry tongue in a child with scarlet fever caused by strep pharyngitis; note marked erythema and prominent papillae. (Courtesy of Richard P. Usatine, MD.)

DIFFERENTIAL DIAGNOSIS

The rash of scarlet fever may be confused with the following:

- Allergic/contact dermatitis—Often localized to areas of contact; prominent pruritus and skin vesicles often in linear streaks (see Chapter 145, Atopic Dermatitis and Chapter 146, Contact Dermatitis).
- Viral exanthem—Many viral exanthems have prodromal phases with fever followed by skin rashes that can be macular or maculopapular including measles (see Chapter 126, Measles), rubella (tender retroauricular, cervical, and occipital lymphadenopathy, and rash starts on face and spreads and fades quickly), and roseola (rash occurs at the end of a period of 3 to 5 days of high fever). Lack of sandpaper feel and oral findings help distinguish.
- Staphylococcal scalded skin syndrome—Rash may also follow a prodrome of malaise and fever but is macular, brightly erythematous, and initially involves the face, neck axilla, and groin. Skin is markedly tender and large areas of the epidermis peel away.
- Erythema toxicum—Rash of newborns; often blotchy, evanescent, macular erythema that can include pale yellow or white wheals or papules on an erythematous base (see Chapter 108, Normal Skin Changes).

The differential diagnosis for strawberry tongue includes:

- Kawasaki disease (**Figure 34-5**)—Fever persists at least 5 days and there must be the presence of at least four principal features including the following:⁴
 - Changes in extremities—Acute: Erythema of palms, soles; edema of hands and feet. Subacute: Periungual peeling of fingers and toes in weeks 2 and 3.
 - Polymorphous exanthem.
 - Bilateral bulbar conjunctival injection without exudate.
 - Changes in lips and oral cavity—Erythema, lips cracking, strawberry tongue, diffuse injection of oral and pharyngeal mucosae.
 - Cervical lymphadenopathy (>1.5 cm diameter), usually unilateral.
- Viral stomatitis with eruptive lingual papillitis—Lack of other features for scarlet fever or Kawasaki's will assist in differentiating.
- Red-colored food dyes—History is helpful; edema and prominent papillae will be absent.

FIGURE 34-5 Child recovering from Kawasaki's disease. Note the conjunctival injection that still remains. (Courtesy of Greg Thompson, MD.)

MANAGEMENT

NONPHARMACOLOGICAL

- Supportive care with oral fluids and age-appropriate symptomatic measures, such as salt-water gargles, and an antipyretic as needed are recommended.

MEDICATIONS

- For scarlet fever and strawberry tongue caused by group A *Streptococcus*:
 - Oral penicillin (penicillin VK 500 mg divided twice daily or 250 mg divided 4 times daily for 10 days for adults or 25 to

50 mg/kg per day divided 4 times daily for 10 days for children) or macrolide (erythromycin base 500 mg 4 times daily for 10 days for adults or erythromycin estolate 20 mg/kg per day or succinate 40 mg/kg per day divided twice daily for 10 days for children) in penicillin-allergic patients for 10 days.⁵ **SOR A**

- Cephalosporins are an efficacious alternative (e.g., cefuroxime axetil 250 mg twice daily for 10 days for adults or 20 mg/kg per day divided twice daily for 10 days for children); cephalosporins were better than penicillin in a metaanalysis.⁶ **SOR A**
- Symptoms typically resolve in 4 to 7 days.
- For strawberry tongue caused by Kawasaki disease:
 - Intravenous gammaglobulin (IVIG), 2 g/kg in a single infusion, within 7 to 10 days of onset for Kawasaki disease to reduce subsequent coronary artery abnormalities.⁴ **SOR A** Additional IVIG infusion may be considered if defervescence is not achieved in the first 1 to 2 days.⁷
 - In the acute phase, aspirin is also administered at 80 to 100 mg/kg per day in 4 doses with IVIG followed by low-dose aspirin (3 to 5 mg/kg per day) until the patient shows no evidence of coronary changes by 6 to 8 weeks after the onset of illness.⁴ **SOR C**

REFERRAL OR HOSPITALIZE

- Hospitalization should be considered if a patient is dehydrated or exhibits cardiorespiratory instability. It should also be considered for cases of complicated scarlet fever, streptococcal toxic shock, staphylococcal scalded skin, rheumatic fever, acute glomerulonephritis, or Kawasaki disease (when suspected).
- Cardiology, infectious disease, or nephrology consultation may be indicated in the most severe cases.

PROGNOSIS

Scarlet fever usually follows a benign course. Rarely it is complicated by septic shock and multi-organ failure, suppurative complications such as peritonsillar abscess, or nonsuppurative complications such as rheumatic fever or poststreptococcal glomerulonephritis

FOLLOW-UP

- Routine follow-up is not required unless illness is protracted or a complication is suspected.
- For patients with uncomplicated Kawasaki disease, echocardiographic evaluation should be performed at the time of diagnosis, at 2 weeks, and at 6 to 8 weeks after onset of the disease.⁴ **SOR C** Recent studies show that repeat echocardiography performed 1 year after the onset of the illness is unlikely to reveal coronary artery enlargement in patients whose echocardiographic findings were normal at 4 to 8 weeks.⁴

PATIENT EDUCATION

- Contact physician for fever recurrence, atypical or persistent rash, and new symptoms or potential complications (meningitis, sinusitis,

otitis media, oropharyngeal abscess, pneumonia, acute glomerulonephritis, or rheumatic fever).

- Completion of a prescribed antibiotic course is encouraged to decrease the incidence of recurrence and potential complications.³

35 PHARYNGITIS

Brian Williams, MD
Richard P. Usatine, MD
Mindy A. Smith, MD

PATIENT STORY

A 27-year-old woman complains of 2 days of sore throat, fever, and chills. She is unable to swallow anything other than liquids because of severe odynophagia. She denies any congestion or cough. On examination, she has bilateral tonsillar erythema and exudate (**Figure 35-1**). Her anterior cervical lymph nodes are tender. Based on the presence of fever, absence of cough, tender lymphadenopathy, and tonsillar exudate, she is diagnosed with a high probability of group A β -hemolytic *Streptococcus* (GABHS) pharyngitis and prescribed antibiotics.

INTRODUCTION

Pharyngitis is inflammation of the pharyngeal tissues, and is usually associated with pain. The complaint of “sore throat” is a common one in the primary care office, and can be accompanied by other symptoms and signs including throat scratchiness, fever, headache, malaise, rash, joint and muscle pains, and swollen lymph nodes.

EPIDEMIOLOGY

- Pharyngitis accounts for 1% of primary care visits.¹
- Viral infections account for an estimated 60% to 90% of cases of pharyngitis.
- Bacterial infections are responsible for between 5% and 30% of pharyngitis cases, depending upon the age of the population and the season.
- The GABHS accounts for 5% to 10% of pharyngitis in adults and 15% to 30% in children.² Up to 38% of cases of tonsillitis are because of GABHS.
- Highest prevalence in winter.
- Highest incidence in children between the ages of 4 and 7 years.
- Acute rheumatic fever is currently rare in the United States.
- Up to 14% of deep neck infections result from pharyngitis.³

ETIOLOGY AND PATHOPHYSIOLOGY

- Some viruses, such as adenovirus, cause inflammation of the pharyngeal mucosa by direct invasion of the mucosa or secondary to suprapharyngeal secretions.⁴ Other viruses, such as rhinovirus, cause pain through stimulation of pain nerve endings by mediators, such as bradykinin.
- The GABHS releases exotoxins and proteases. Erythrogenic exotoxins are responsible for the development of the scarlatiniform exanthem (**Figure 35-2**).⁵ Secondary antibody formation because of cross-reactivity may

FIGURE 35-1 Strep pharyngitis showing tonsillar exudate and erythema. (Courtesy of Michael Nguyen, MD.)

FIGURE 35-2 Scarlatiniform rash in scarlet fever. This 7-year-old boy has a typical sandpaper rash with his strep throat and fever. The erythema is particularly concentrated in the axillary area. (Courtesy of Richard P. Usatine, MD.)

result in rheumatic fever and valvular heart disease.⁶ Antigen–antibody complexes may lead to acute poststreptococcal glomerulonephritis.

- Untreated GABHS pharyngitis can result in suppurative complications including bacteremia, otitis media, meningitis, mastoiditis, cervical lymphadenitis, endocarditis, pneumonia, or peritonsillar abscess formation (**Figure 35-3**). Nonsuppurative complications include rheumatic fever and poststreptococcal glomerulonephritis.

RISK FACTORS

- Immune deficiency.
- Chronic irritation (e.g., allergies, cigarette smoking).

DIAGNOSIS

CLINICAL FEATURES

- Rhinorrhea and cough are more consistent with viral etiology.
- Rapid onset odynophagia, tonsillar exudates, anterior cervical lymphadenopathy, and fever are consistent with streptococcal pharyngitis.
- Not all tonsillar exudates are caused by streptococcal pharyngitis. Mononucleosis and other viral pharyngitis can cause tonsillar exudates (**Figures 35-4** and **35-5**). The positive predictive value for tonsillar exudate in strep throat is only 31%; that is, 69% of patients with tonsillar exudate will have a nonstreptococcal cause.
- Para- and supratonsillar edema with medial and/or anterior displacement of the involved tonsil and uvular displacement to the contralateral side suggest peritonsillar abscess (**Figure 35-3**). Trismus and anterior cervical lymphadenopathy with severe tenderness to palpation are additional findings.
- Palatal petechiae can be seen in all types of pharyngitis (**Figure 35-6**).
- A sandpaper rash is suggestive of scarlet fever (**Figure 35-2**, and Chapter 34, Scarlet Fever and Strawberry Tongue).
- Lymphoid hyperplasia can cause a cobblestone pattern on the posterior pharynx or palate from viral infections, gastroesophageal reflux disease (GERD), or allergies (**Figure 35-7**). Although it usually is more suggestive of a viral infection or allergic rhinitis, lymphoid hyperplasia can be seen in strep pharyngitis (**Figure 35-8**).
- The following criteria are helpful in the diagnosis of GABHS pharyngitis:^{7–10}
 - History of fever or temperature of 38°C (100.4°F) (1 point).
 - Absence of cough (1 point).
 - Tender anterior cervical lymph nodes (1 point).
 - Tonsillar swelling or exudates (1 point).
 - Age:
 - <15 years (1 point).
 - 15 to 45 years (0 points).
 - >45 years (–1 point).

The probability of GABHS is approximately 1% with –1 to 0 points and approximately 51% with 4 to 5 points.¹¹

LABORATORY TESTS AND IMAGING

- Rapid antigen detection is often used to diagnose GABHS. Test options include enzyme immunoassays, latex agglutination, liposomal method, and immunochromatograph assays; the latter has the highest reported sensitivity (0.97), specificity (0.97), and positive (32.3) and negative (0.03) likelihood ratios.¹²
- The gold standard for the diagnosis of streptococcal infection is a positive throat culture. However, GABHS is part of the normal oropharyngeal flora in many patients and the diagnosis of acute streptococcal pharyngitis must include both the clinical signs of acute infection and a positive throat culture.
- False-positive tests for streptococcal infection can occur when the patient is colonized with GABHS but is not the cause of the acute disease.
- False-negative tests for streptococcal infection can occur when poor sampling technique with the throat swab fails to recover the streptococcal organism when it is the cause of the acute infection.
- A positive mono spot (likelihood ratio in the first week of illness 5.7) and/or greater than 40% atypical lymphocytes on the peripheral smear (likelihood ratio: 39) indicate mononucleosis.¹²
- Viral cultures obtained from vesicles can be obtained in Coxsackievirus and herpes infections, but the diagnosis is usually based on clinical suspicion and findings.
- Head–neck CT scan can assist in the diagnosis and localization of peritonsillar abscess and should be obtained if further extension into the deeper neck is suspected.¹³

DIFFERENTIAL DIAGNOSIS

- Infectious mononucleosis—Nausea, anorexia without vomiting, uvular edema, generalized symmetric lymphadenopathy, and lethargy particularly in teenagers and young adults, is more suggestive of acute mononucleosis (Epstein-Barr virus [EBV]) although the pharyngeal examination has a similar appearance to GABHS (**Figure 35-4**). Hepatosplenomegaly is indicative of EBV in this group.
- Herpangina/Coxsackievirus infection—Oropharyngeal vesicles and ulcers indicate herpangina, which is caused by Coxsackievirus A16 in the majority of cases (**Figure 35-9**).
- Oral *Candida*—Whitish plaques of the oropharyngeal mucosa indicate oral *Candida*/thrush, which is mainly found in infants but can be found in adults with immunosuppression (see Chapter 136, *Candidiasis*).
- Sexually transmitted infections—Primary human immunodeficiency virus, gonococcal and syphilitic pharyngitis can all present with the symptom of sore throat. Although uncommon, these diagnoses should be considered in high-risk populations.
- Primary herpes gingivostomatitis causes oral ulcers and pain in the mouth. The wide distribution of ulcers with the first case of herpes simplex virus (HSV)-1 distinguishes this infection from other types of pharyngitis (see Chapter 129, Herpes Simplex).
- *Cytomegalovirus* (CMV)—Primary CMV infection in the immunocompetent host is usually asymptomatic. In the immunocompromised host, CMV may present with a mononucleosis-like syndrome clinically indistinguishable from EBV infection.

FIGURE 35-8 Strep pharyngitis with dark necrotic area on right tonsil and prominent lymphoid hyperplasia in a cobblestone pattern on the posterior pharynx. (Courtesy of Richard P. Usatine, MD.)

FIGURE 35-9 Herpangina caused by Coxsackievirus A16.

- Deep neck infections—Asymmetry of the neck, neck masses, and any displacement of the peripharyngeal wall should raise suspicion. Associated shortness of breath may be a warning sign of impending airway obstruction. Other complications include aspiration, thrombosis, mediastinitis, and septic shock.¹³
- Epiglottitis—Rapid-onset fever, malaise, sore throat, and drooling in the absence of coughing characterize acute epiglottitis, especially when presenting in children. Progression of the disease can lead to life-threatening airway obstruction. Fortunately, this is a rare condition because of the preventive effect of the *Haemophilus influenzae* type b (HIB) vaccine.
- Supraglottitis—Similar symptoms to epiglottitis, although seen in adults. Sore throat and painful swallowing are the most common presenting symptoms, seen in more than 90% of cases. Muffled voice and drooling, dyspnea, stridor, and cough reported in less than 50% of cases. No definite organism is identified in the majority of cases. Unlike epiglottitis in children, HIB is responsible for less than 20% of adult cases but still accounts for the majority of positive cultures. Mortality rates have been reported up to 20%. Currently more common than epiglottitis, because of HIB vaccine.
- Diphtheria—A rare condition in the United States today, as most patients have been immunized. However, it needs to be considered, especially in unvaccinated and immigrant populations. Pharyngeal diphtheria presents with sore throat, low-grade fever, and malaise. The pharynx is erythematous with a grayish pseudomembrane that cannot be scraped off. Complications include myocarditis resulting in acute and severe congestive heart failure (CHF), endocarditis, and neuropathies.
- Other bacterial causes— Non-group A *Streptococcus*, *Fusobacterium necrophorum*, *Mycoplasma pneumoniae*, *Chlamydia pneumoniae*, and *Arcanobacterium haemolyticum* have all been isolated as bacterial causes of pharyngitis; not as clinically significant, but all generally respond to treatments prescribed for strep pharyngitis.

MANAGEMENT

NONPHARMACOLOGICAL

- Hydration with plenty of liquids (children and adults).
- Salt-water gargles (children and adults).
- Lozenges for comfort (adults only).

MEDICATIONS

- Age-appropriate dosing of acetaminophen and ibuprofen may be used for symptomatic relief of fever and pain. Doses can be alternated as needed.
- Steroids (e.g., dexamethasone single 10-mg injection) are indicated in severe tonsillitis in patients without immunocompromise.¹² **SOR C** However, there is no good evidence to recommend steroids in infectious mononucleosis.¹⁴
- In extreme cases of pharyngitis, 1 teaspoon of viscous lidocaine 2% in a half glass of water gargled 20 to 30 minutes before meals helps theodynophagia. This is typically only recommended in rare cases because of risk of aspiration, potential toxicity of lidocaine, and the

risk for oral mucosal burns—consider hospitalization if symptoms are this severe.

- Antibiotic use—Use the clinical prediction rule (given above [see “Clinical Features”]) for estimating the probability of GABHS:^{7–11}
 - Low probability (no test, no treatment for GABHS): Patients scoring 0 points should be treated symptomatically and not given antibiotics.
 - Intermediate probability (test and treatment based on result): Patients with 1 to 3 points (probability of GABHS is approximately 18%) should undergo a rapid antigen test and be treated with antibiotics if positive.
 - High probability (no test, treatment for GABHS): Patients with 4 to 5 points should be considered for empiric antibiotic treatment.
- For suspected or proven GABHS, penicillin V 500 mg orally 2 to 3 times daily for 10 days continues to be the treatment of choice for adults.¹⁵ Erythromycin 500 mg orally 4 times daily may be used in penicillin allergic patients. Penicillin G 1.2 million U IM single dose may be used if unable to tolerate oral medication. Pediatric doses are Pen VK 25 to 50 mg/kg per day divided 3 to 4 times daily and erythromycin 30 to 50 mg/kg per day divided 4 times daily for 10 days. In some cases amoxicillin 25 mg/kg per day in divided doses every 12 hours is preferred because of palatability.
- Penicillin G (600 mg IV every 6 hours for 24 to 48 hours) in combination with metronidazole (15 mg/kg IV more than 1 hour followed by 7.5 mg/kg IV more than 1 hour every 6 to 8 hours) is recommended for peritonsillar abscess.

REFERRAL

- If signs of airway impairment are present, the patient should be immediately transported to an emergency department. Intubation can be extremely difficult and risky.
- Refer patients with peritonsillar abscess to ear, nose, and throat (ENT). Incision and drainage is the treatment of choice in addition to using systemic antibiotics.
- Consider ENT referral for tonsillectomy in proven recurrent GABHS cases, or under certain other conditions (e.g., antibiotic allergies/intolerances) with recurrence.¹⁶ However, there is no evidence to support tonsillectomy for isolated cases.¹⁷

PROGNOSIS

- Sore throat, regardless of the cause, is typically self-limiting. Typical symptoms last 3 to 4 days.
- Longer-term complications are rare but antibiotic treatment to prevent these sequelae remains justification for treatment. Antibiotics shorten the duration of illness by approximately 1 day and can reduce the risk of rheumatic fever by approximately two-thirds in communities where this complication is common.¹⁵ However, GI symptoms like mild diarrhea are common side effects of antibiotic therapy. The number needed to treat to prevent 1 sore throat at day 3 is less than 6; at week 1 it is 21.¹⁵

FOLLOW-UP

Follow up if clinically deteriorating, especially if swallowing or breathing becomes more difficult or severe headache develops.

PATIENT EDUCATION

- The treatment for most cases of non-GABHS pharyngitis is education. Explain to patients the difference between a viral and a bacterial infection to help them understand why antibiotics were prescribed or not prescribed. Antibiotic treatment for a patient with an obvious viral infection is inappropriate, despite patient requests. Studies demonstrate that spending time with the patient to explain the disease process is associated with greater patient satisfaction than prescribing an antibiotic.^{18,19}
- Rest, liquids, and analgesics should be encouraged.
- Patients receiving antibiotics should be reminded to complete the entire course, even if symptoms improve. Common antibiotic side effects, like rash, nausea, and diarrhea, should be reviewed.
- Patients with mononucleosis and splenomegaly should be warned to avoid contact sports because of the risk of splenic rupture.

36 THE LARYNX (HOARSENESS)

Laura Matrka, MD
C. Blake Simpson, MD
J. Michael King, MD

PATIENT STORY

A 47-year-old man with a 40-pack-year history of smoking presents with worsening hoarseness that began approximately 6 weeks ago. He complains of globus sensation and difficulty swallowing solid foods. He denies odynophagia, otalgia, hemoptysis, and hematemesis. There is no associated cough, and he has not had any constitutional symptoms such as fevers, chills, or recent weight loss.

Hoarseness in a middle-aged man with the above symptoms is very common, and the differential diagnosis is long (all the diseases below are possibilities in this case scenario). The patient's smoking history and duration of symptoms should raise concern for a possible laryngeal malignancy. However, there is a higher incidence of laryngopharyngeal reflux (LPR) followed by benign vocal fold (cord) lesions.

INTRODUCTION

The evaluation of hoarseness typically involves first ruling out the most serious pathologies, such as laryngeal squamous cell carcinoma, in adults or recurrent respiratory papillomatosis in children, and then proceeding with a more focused and subtle evaluation to uncover any of the many benign pathologies that affect the larynx. Treatment of these benign pathologies must take into account the patient's lifestyle and voice needs. It also often incorporates education on vocal hygiene, which involves increasing hydration, decreasing mucus and vocal abuse, and reducing acid reflux if a factor.

SYNONYMS AND DEFINITIONS

- Hoarseness, dysphonia, vocal strain, breathiness, raspiness.
- Vocal cords, true vocal cords, true vocal folds, glottis (**Figure 36-1**).
- False vocal folds, false vocal cords (mucosal folds in the supraglottis, just superior to the true vocal folds and separated from the true folds by the ventricle).
- Flexible fiberoptic laryngoscopy, direct laryngoscopy, nasopharyngeal scope (NP scope), transnasal fiberoptic laryngoscopy.
- Stroboscopy, videolaryngostroboscopy (VLS), strobe exam.

EPIDEMIOLOGY

- The most common cause of hoarseness in adults and children overall is viral infection causing laryngitis (**Figure 36-2**).

FIGURE 36-1 Normal larynx (true and false vocal folds). FVF, False vocal fold; TVF, true vocal fold (cord). (Courtesy of C. Blake Simpson, MD.)

FIGURE 36-2 Laryngitis—diffuse erythema and inflammation, irregular vocal fold edges. (Courtesy of C. Blake Simpson, MD.)

- LPR disease may be present in up to 50% of patients presenting with voice and laryngeal disorders.¹ It is less commonly the sole cause of hoarseness.
- Squamous cell carcinoma (SCC) accounts for 95% of laryngeal cancer. Approximately 11,000 new cases are diagnosed in the United States each year. Peak incidence is in the sixth and seventh decades of life with a strong male predominance.¹
- Recurrent respiratory papillomatosis (RRP) represents the most common benign neoplasm of the larynx among children and should be considered in children with chronic hoarseness. A known risk factor for juvenile onset is the triad of a firstborn child (75%), teenage mother, and vaginal delivery. The incidence is 4.3 per 100,000 children and 1.8 per 100,000 adults.² There is a known association between cervical human papillomavirus (HPV) infection in the mother and juvenile onset RRP, but the precise mode of transmission is unclear. The risk of a child contracting RRP after delivery from an actively infected mother with genital HPV ranges from 0.25% to 3%.³ Because cesarean section does not prevent RRP in all cases, routine prophylactic cesarean section in mothers with active condyloma acuminata is currently *not* recommended.

ETIOLOGY AND PATHOPHYSIOLOGY

- Laryngitis is a nonspecific term to describe inflammation of the larynx from any cause. Most commonly this is due to a viral upper respiratory infection. Compare the anatomy of the normal larynx (**Figure 36-1**) with that of acute laryngitis (**Figure 36-2**), with the primary differences being in the diffuse erythema and edema of the vocal folds and the often transient irregularities of the vocal fold medial edge as compared to the straight medial edge of the normal vocal fold. Laryngeal symptoms result from dry throat, mucous stasis, and recurrent trauma from coughing and throat clearing.
- LPR must be differentiated from gastroesophageal reflux disease (GERD), in which acid reflux is more likely to cause heartburn, indigestion, and regurgitation and does not necessarily reach the larynx or upper aerodigestive tract. LPR is more likely to present with frequent throat clearing, dry cough, hoarseness, and globus sensation, and does not include heartburn in more than 60% of patients. The larynx is highly sensitive to even small amounts of acid or pepsin. Thus, patients who do not have severe enough reflux to cause esophagitis, with its associated symptoms of GERD, may still develop symptomatic laryngeal mucosal injury, with its associated symptoms of LPR.^{1,4,5,8}
- SCC has a multifactorial etiology, but 90% of patients have a history of heavy tobacco and/or alcohol use. These risk factors have a synergistic effect. Other independent risk factors include employment as a painter or metalworker, exposure to diesel or gasoline fumes, and exposure to therapeutic doses of radiation.
- RRP is caused by HPV-6 and HPV-11. Onset is predominantly in young children, although an adult-onset variant exists. Its course is unpredictable and highly variable. Tracheal and bronchopulmonary spread can occur, as can malignant transformation to SCC; the latter is rare. Bronchopulmonary spread is uniformly fatal as a consequence of the lack of surgical options.

- Vocal cord nodules are benign lesions arising from mechanical trauma (vocal abuse or misuse) and are often described as a “callous” of the vocal folds. Vocal cord polyps or cysts can arise from vocal abuse, a blocked mucous gland, vocal fold hemorrhage, a background of polypoid corditis (see below), or idiopathic etiologies. They are a common cause of dysphonia in singers, teachers, and other professional voice users. Vocal cord granulomas are associated with LPR and/or intubation trauma and rarely require surgery.
- Causes of vocal cord paresis or paralysis are myriad:^{1,6}
 - Iatrogenic surgical injury (anterior spine fusion, carotid endarterectomy, thyroidectomy) is most common (25%).
 - Nonlaryngeal malignancy (mediastinal, bronchopulmonary, and skull base) (24%).
 - No identifiable cause (idiopathic), often assumed to be viral (20%).
 - Nonsurgical trauma (penetrating/blunt injury and intubation injury) (10%).
 - Neurologic causes (stroke, central nervous system [CNS] tumors, multiple sclerosis [MS], and amyotrophic lateral sclerosis [ALS]) (8%).
 - Inflammatory/infectious disease (2% to 5%).
- Presbyphonia is a diagnosis of exclusion denoting vocal changes from aging of the larynx (gradually weakening voice, poor vocal projection, and vocal “roughness”). Hoarseness in patients older than 60 years of age is most commonly a result of benign vocal fold lesions followed by malignancy and vocal fold paralysis. Once a thorough evaluation has been done to rule out organic causes, presbyphonia is the cause of hoarseness in approximately 10% of elderly patients; it is characterized by atrophied vocal folds.⁷

DIAGNOSIS

CLINICAL FEATURES

- Key historical and physical examination findings can help differentiate benign pathology from potentially more serious problems:
 - Otolgia (ear pain)—Often a source of referred pain from primary laryngeal and pharyngeal carcinomas; it is not typically seen with benign pathologies.
 - Dysphagia and odynophagia (pain when swallowing)—Nonspecific complaints, but potentially worrisome for obstructing lesions or reactive pharyngeal edema.
 - Stridor or dyspnea—“Noisy breathing” with respiratory distress should be evaluated urgently to rule out impending airway obstruction. Less-severe dyspnea may be noted by patients with vocal cord paralysis caused by air escape during speech; a detailed history should reveal that it occurs only during speech or from the inability to perform adequate Valsalva maneuver as a result of loss of tight glottic closure.
 - Globus pharyngeus—The persistent or intermittent nonpainful sensation of a lump or foreign body in the throat. This is commonly associated with LPR.
 - Neck mass—Associated unilateral or bilateral lymphadenopathy is suspicious for a laryngeal neoplasm until proven otherwise.
 - Timing—Onset, duration, and frequency of symptoms is important.
- Red flags for laryngeal carcinoma include a history of smoking and/or alcohol abuse, associated neck mass, weight loss or severe

dysphagia, presence of stridor (often initially noted with sleep or when lying flat), and otalgia.

- LPR symptoms include hoarseness, throat clearing, “postnasal drip,” chronic cough, dysphagia, globus pharyngeus, and sore throat. “Heartburn” is *not* a requisite symptom!
- Hallmark of diagnosis is direct visualization of the larynx, often performed by an otolaryngologist with a flexible laryngoscopic exam. Stroboscopy is added to the evaluation when visualization of the mucosal wave of the vocal folds is necessary. Assessment of the mucosal wave aids in determining the depth of a lesion within the vocal fold and the severity of its effect on the voice.

LABORATORY AND IMAGING

- Laboratory studies are not usually helpful, except in the rare case that a previously undiagnosed rheumatologic disease presents with vocal complaints as the initial symptom.
- Plain films of the chest are useful to rule out bronchopulmonary or mediastinal masses as a cause of vocal cord paralysis, but are generally not helpful for primary laryngeal lesions.
- A CT of the neck and chest with contrast is useful in ruling out pathology along the length of the recurrent laryngeal nerve in cases of unexplained vocal cord paralysis and in cases suspicious for carcinoma, especially if there is associated cervical lymphadenopathy. A chest X-ray is sometimes used to replace the chest CT.
- An MRI with and without gadolinium offers the best imaging for suspected primary CNS or skull base lesions; this is typically added to the work-up for vocal cord paralysis when evidence of high vagal injury such as weakness in palate elevation is present.
- Referral to a gastroenterologist for *dual-channel* 24-hour pH probe monitoring (*while on antireflux medications*) is a useful diagnostic tool for patients with suspected LPR.

DIFFERENTIAL DIAGNOSIS

- Laryngitis (**Figure 36-2**).
- Laryngopharyngeal reflux (**Figures 36-3 and 36-4**).
- SCC (**Figure 36-5**).
- Laryngeal papillomatosis (**Figures 36-6 and 36-7**).
- Vocal cord nodule (**Figure 36-8**).
- Vocal cord polyp (**Figure 36-9**).
- Vocal cord cyst.
- Vocal cord paresis or paralysis.
- Presbyphonia.
- Neurologic disorders (MS, Parkinson disease, ALS, and essential tremor).
- Systemic diseases (Wegener granulomatosis, sarcoidosis, rheumatoid arthritis).

MANAGEMENT

- Laryngitis—Empiric treatment is aimed at alleviating symptoms such as cough and thinning nasal/pharyngeal secretions. Hydration

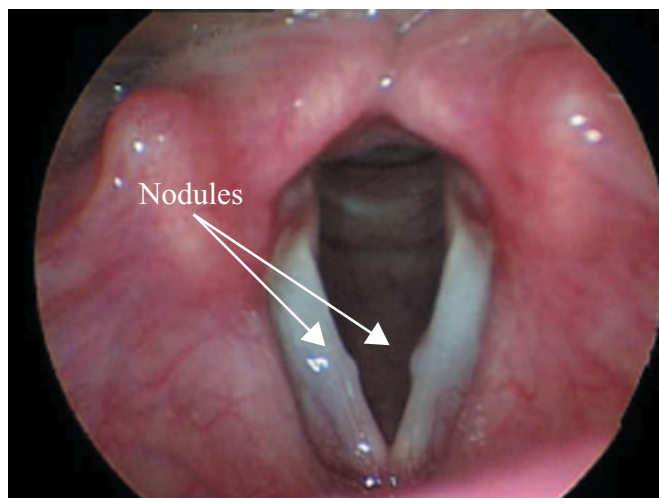

FIGURE 36-3 Laryngopharyngeal reflux. Postcricoid region edema (normal is less full and nearly concave) and edema just inferior to the true vocal fold edge (infraglottic edema) indicative of chronic inflammation from reflux, often called “pseudosulcus.” Other findings of LPR not seen in this image include thick mucus and mucosal erythema. (Courtesy of C. Blake Simpson, MD.)

FIGURE 36-4 Laryngopharyngeal reflux during phonation with diffuse erythema, inflammation, and thick mucus. (Courtesy of C. Blake Simpson, MD.)

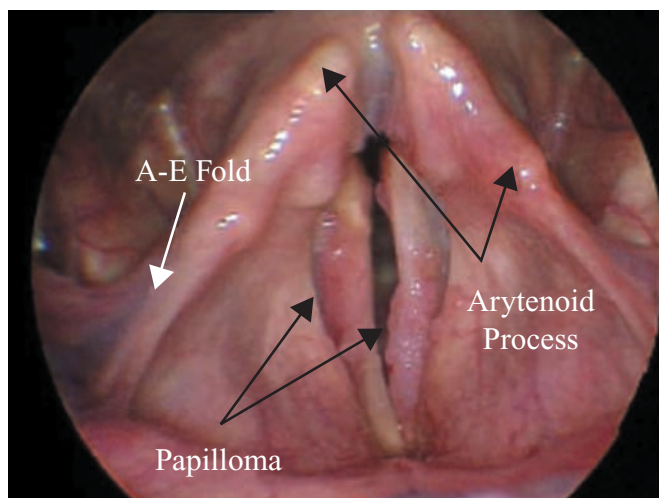

FIGURE 36-5 Squamous cell carcinoma, advanced stage with left true vocal cord paralysis. (Courtesy of C. Blake Simpson, MD.)

is critical for healing (increased water intake, steam showers, humidifiers, and saunas may help). Throat clearing should be discouraged and voice rest encouraged. Talking should be conserved, not prohibited. Inform patients that whispering causes even more vocal strain than normal speech.

- Vocal cord nodules, polyps, and cysts—Initial management involves speech therapy accompanied by medical treatment of dehydration, allergies, sinonasal secretions (postnasal drip), and LPR. Refractory disease may require surgical excision.
- Laryngeal papillomatosis—Most children have a recalcitrant course that requires periodic surgical debridement by an otolaryngologist to prevent airway obstruction. Spontaneous remission may occur. Adjuvant therapy, such as intraepithelial injection of cidofovir at the time of surgery, is commonly utilized in more aggressive disease. It is hoped that the administration of the Gardasil vaccine will decrease the incidence of RRP over time. Some practitioners administer the Gardasil vaccine in a nonprophylactic manner to patients with existing RRP, although there is no strong evidence currently to support a treatment effect of the vaccine.^{2,3}
- LPR—Mainstay treatment involves patient education to modify diet and behavior (avoidance of acidic or greasy foods, tobacco cessation, limiting alcohol and caffeine, weight loss, and avoiding meals shortly before lying down). Medical therapy consists of *twice* daily proton pump inhibitors (PPIs) 30 to 60 minutes before meals, which can often be weaned after several months of therapy. Some patients benefit from adding an H₂-blocker, such as ranitidine 300 mg, at bedtime.
- SCC—Multidisciplinary management is best. Depending on the staging and extent of disease, patients often receive one or more modalities of treatment including surgery, radiation, and chemotherapy.
- Vocal cord paresis or paralysis—Treatment is targeted at the underlying disorder. Some patients may be candidates for surgical intervention to reposition the paralyzed cord medially with an implant. With a mobile vocal fold on the contralateral side, airway is rarely compromised by medialization of the paralyzed vocal fold. These procedures restore voice quality and often alleviate chronic aspiration problems.
- Neurologic diseases—Laryngeal complaints can be associated with MS, myasthenia gravis, Parkinson disease, ALS, and essential tremor. In addition to managing the underlying disorder, a trial of voice therapy is sometimes useful.
- Systemic diseases—Diseases such as Wegener granulomatosis, sarcoidosis, relapsing polychondritis, and rheumatoid arthritis rarely may involve the larynx. Voice and swallowing problems in these patients should be evaluated by an otolaryngologist for possible therapies to improve the voice and to rule out associated airway stenosis.
- Presbyphonia—This is a diagnosis of exclusion. Once organic etiologies have been ruled out, a trial of voice therapy is recommended before considering surgical options, such as vocal fold injection augmentation to plump the atrophied vocal fold.

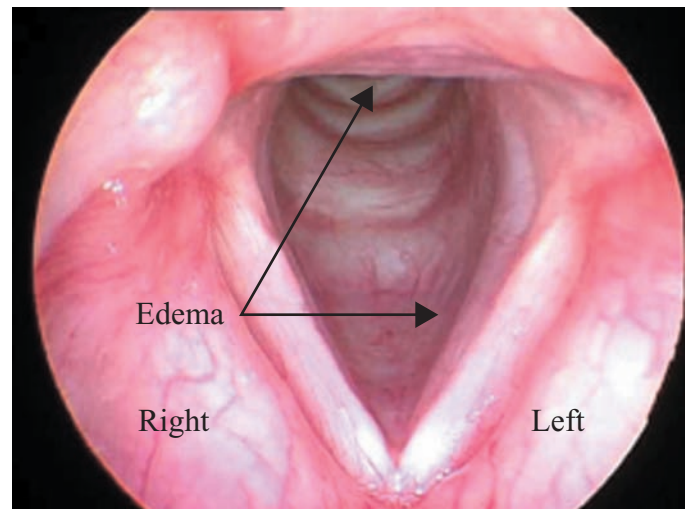

FIGURE 36-7 Recurrent respiratory papillomatosis in a 3-year-old child. The papillomas are nearly obstructing the airway and have required debridement. (Courtesy of C. Blake Simpson, MD.)

FIGURE 36-8 Vocal cord nodules. (Courtesy of C. Blake Simpson, MD.)

FOLLOW-UP

- Urgent referral to an otolaryngologist for flexible laryngoscopic examination of the larynx is advisable when the history and physical are suspicious for carcinoma.
- When symptoms worsen or fail to resolve, referral to an otolaryngologist (or laryngologist) is indicated (see “Provider Resources” below to find a laryngologist in your area).
- Patients suspected of having LPR should be seen approximately 6 to 8 weeks after initiating empiric therapy with a PPI and lifestyle measures. An otolaryngology and/or gastroenterology consultation is indicated when symptoms do not improve after optimized behavioral and medical management or for patients who require long-term PPI therapy (longer than 12 months). Some of these patients, particularly those with chronic cough or longstanding requirement for PPIs, may require transnasal esophagoscopy (performed in the otolaryngologist’s office) or esophagogastroduodenoscopy (performed by a gastroenterologist in the endoscopy suite). Recent evidence has pointed to chronic cough as an independent indicator of esophageal adenocarcinoma, and Barrett esophagus should be ruled out in any patient requiring long-term PPI use.⁹

PATIENT EDUCATION

- In cases of nonmalignant pathology, vocal hygiene and other lifestyle measures often play an important role in treatment. Efforts should focus on increasing hydration, decreasing caffeine intake, tobacco cessation, and prevention of excessive alcohol use.
- Vocal cord nodules, polyps, and cysts typically occur in professional voice users (ministers, auctioneers, teachers, singers, etc.). Speech therapists can be integral in preventing and healing lesions by teaching patients how to avoid vocal misuse.
- Benign laryngeal pathology may be improved, but not necessarily resolved, by controlling both gastroesophageal and LPR disease. Patients should be educated about GERD/LPR risk factors:
 - Spicy, acidic, or greasy foods.
 - Tobacco and alcohol abuse.
 - Caffeinated beverages (especially carbonated sodas).
 - Citric juices, tomato sauces, chocolate, mints.
 - Obesity.
 - Eating meals within 2 to 3 hours of lying down.

37 BLACK HAIRY TONGUE

Richard P. Usatine, MD
Wanda C. Gonsalves, MD

PATIENT STORY

A 60-year-old man who smokes presents to the physician's office smelling of alcohol. He complains of a black discoloration of his tongue and a gagging sensation on occasion. He admits to smoking 1 to 2 packs per day along with drinking at least 6 to 8 beers per day. The patient brushes his teeth infrequently and has not seen a dentist for a long time. On physical exam, his teeth are stained and his tongue shows elongated papillae with brown discoloration (**Figure 37-1**). Diagnoses include black hairy tongue (BHT), poor oral hygiene, and tobacco and alcohol addiction.

INTRODUCTION

BHT is a benign disorder of the tongue characterized by abnormally hypertrophied and elongated filiform papillae on the surface of the tongue.¹ In addition, there is defective desquamation of the papillae on the dorsal tongue resulting in a hair-like appearance.²

SYNONYMS

Hyperkeratosis of the tongue, lingua villosa nigra.

EPIDEMIOLOGY

The prevalence of BHT varies depending upon the risk factors in the population being studied.

- It can be as high as 57% in persons incarcerated or addicted to drugs.³
- The prevalence in Minnesota schoolchildren was 0.06%.⁴
- Turkish dental patients showed higher rates of BHT in men, smokers, and black tea drinkers. The highest prevalence was 54% in heavy smokers.⁵

ETIOLOGY AND PATHOPHYSIOLOGY

- BHT (**Figure 37-1**) is a disorder characterized by elongation and hypertrophy of filiform papillae and defective desquamation of the papillae.^{2,6}
- These papillae, which are normally about 1 mm in length, may become as long as 12 mm.
 - The elongated filiform papillae can then collect debris, bacteria, fungus, or other foreign materials.¹
- In an extensive literature review of reported cases of drug-induced BHT, 82% of the cases were caused by antibiotics (**Figure 37-2**).¹

FIGURE 37-1 Black hairy tongue showing elongated filiform papillae with brown discoloration in a man who is a heavy smoker and drinker. Note the tobacco-stained teeth. (Courtesy of Brad Neville, DDS.)

FIGURE 37-2 Drug-induced black hairy tongue with yellowish-brown elongated filiform papillae in a patient taking a broad spectrum antibiotic. (Courtesy of Richard P. Usatine, MD.)

- Dry mouth (xerostomia) from medications, tobacco, and radiation therapy can lead to BHT.¹

RISK FACTORS¹

- Tobacco (smoking and chewing).
- Alcoholism and drug abuse (especially drugs that are smoked).
- Poor oral hygiene.
- Medications (especially antibiotics and those causing xerostomia).
- Oxidizing mouthwashes (containing peroxide).
- Cancer, especially with radiation therapy.
- Drinking black tea or coffee.

DIAGNOSIS

CLINICAL FEATURES

- Patients may be asymptomatic. However, the accumulation of debris in the elongated papillae may cause taste alterations, nausea, gagging, halitosis, and pain or burning of the tongue.¹

The diagnosis is made by visual inspection:

- BHT may exhibit a thick coating of black, brown, or yellow discoloration, depending on foods ingested, tobacco use, and amount of coffee or tea consumed (**Figure 37-3**).

TYPICAL DISTRIBUTION

The lesion is restricted to the dorsum of the tongue, anterior to the circumvallate papillae, rarely involving the tip or sides of the tongue.

LABORATORY TESTS

Consider performing a KOH preparation to rule out associated candidiasis.

DIFFERENTIAL DIAGNOSIS

- Black tongue can occur with the ingestion of bismuth subsalicylate or minocycline. Although the tongue has a black coating, the papillae are not elongated. Without the hypertrophy of papillae this is not a BHT (**Figure 37-4**).
- Hairy leukoplakia—Appears as faint white vertical keratotic streaks typically on the lateral side of the tongue (**Figure 37-5**). Do not confuse BHT with oral hairy leukoplakia, an Epstein-Barr virus–related condition typically affecting the lateral tongue bilaterally in immunocompromised patients, especially those with HIV infection.
- Oral candidiasis—White plaques typically found on the buccal mucosa, tongue, and palate when removed has an erythematous base. The white color should make this easy to distinguish from BHT (see Chapter 136, Candidiasis).

FIGURE 37-3 Black hairy tongue that also is furrowed in a heavy smoker. Note this man also has angular cheilitis, poor dentition and halitosis. (Courtesy of Richard P. Usatine, MD.)

FIGURE 37-4 Black tongue without elongated papillae in a woman with untreated pemphigus vulgaris. Note the palatal erosions along with the black color of the tongue. The black color was gone in 2 days after prednisone was initiated and the patient was able to eat again. (Courtesy of Richard P. Usatine, MD.)

MANAGEMENT

NONPHARMACOLOGIC

- Avoidance of predisposing risk factors (e.g., tobacco, alcohol, and antibiotics). **SOR C**
- Stop the offending medication in drug-induced BHT whenever possible.¹ **SOR B**
- Regular tongue brushing using a soft toothbrush or tongue scraper. **SOR C**

MEDICATIONS

If candidiasis is present, an oral antifungal is indicated. If there is no liver disease, the preferred regimen for oral candidiasis is fluconazole 100 mg daily for 14 days. An alternative is clotrimazole troches 5 times a day for 14 days. Nystatin is less effective. Fluconazole-treated HIV patients with oropharyngeal candidiasis were more likely to remain disease-free than were those treated with other antifungal agents.⁷ **SOR A**

REFERRAL

Patients with poor oral hygiene should be referred to a dentist. All patients should be encouraged to see a dentist at least twice yearly.

PREVENTION

Good oral hygiene and avoidance of risk factors.

PROGNOSIS

BHT is generally a self-limited disorder, so the prognosis should be excellent with good oral hygiene and treatment.

PATIENT EDUCATION

Tell patients to brush their teeth and tongue twice a day or to use a tongue scraper. Address addictions and offer help to quit. Suggest that patients eat firm foods, like fresh apples, that will help to clean the tongue.

38 GEOGRAPHIC TONGUE

Ernest E. Valdez, DDS
Richard P. Usatine, MD
Wanda C. Gonsalves, MD

PATIENT STORY

A 23-year-old male medical student presents to the physician's office complaining of his tongue's "strange appearance." He denies pain or discomfort and is unsure how long the lesions have been present. The lesions seem to change areas of distribution on the tongue. The examination reveals large, well-delineated, shiny and smooth, erythematous spots on the surface of the tongue (**Figure 38-1**). The diagnosis is geographic tongue (benign migratory glossitis). The physician explains that it is benign and that no treatment is needed unless symptoms develop.

INTRODUCTION

Geographic tongue is a recurrent, benign, usually asymptomatic, inflammatory disorder of the mucosa of the dorsum and lateral borders of the tongue. Geographic tongue is characterized by circinate, irregularly shaped erythematous patches bordered by a white keratotic band. The central erythematous patch represents loss of filiform papillae of tongue epithelium. Geographic tongue can, although rarely, present as symptomatic.

SYNONYMS

Benign migratory glossitis, geographic stomatitis.

EPIDEMIOLOGY

- Geographic tongue has an estimated prevalence of 1% to 3% of the population.¹
- It may occur in either children or adults, and exhibits a female predilection.
- Geographic tongue in the United States has a greater prevalence among white and black persons than among Mexican Americans.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Geographic tongue is a common oral inflammatory condition of unknown etiology.
- Some studies have shown an increased frequency in patients with allergies, pustular psoriasis, stress, type 1 diabetes, fissured tongue, and hormonal disturbances.³
- Histopathologic appearance resembles psoriasis.⁴
- Oddly, geographic tongue has an inverse association with cigarette smoking.^{2,5}

FIGURE 38-1 Geographic tongue (benign migratory glossitis). Note the pink continents among the white oceans. (Reprinted with permission from Gonsalves WC, Chi AC, Neville BW. *Common oral lesions: part II*. *Am Fam Phys* 2007;75(4):501-508. Copyright © 2007 American Academy of Family Physicians. All rights reserved.)

DIAGNOSIS

CLINICAL FEATURES

- The diagnosis is made by visual inspection and history of the lesion. The lesions are suggestive of a geographic map (hence geographic tongue) with pink continents surrounded by whiter oceans (**Figure 38-1**).
- Geographic tongue consists of large, well-delineated, shiny, and smooth, erythematous patches surrounded by a white halo (**Figure 38-2**).
- Tongue lesions exhibit central erythema because of atrophy of the filiform papillae and are usually surrounded by slightly elevated, curving, white-to-yellow elevated borders (**Figures 38-1 and 38-2**).
- The condition typically waxes and wanes over time so the lesions appear to be migrating (hence migratory glossitis).
- Lesions may last days, months, or years. The lesions do not scar.
- Most patients are asymptomatic, but some patients may complain of pain or burning, especially when eating spicy foods.
- Suspect systemic intraoral manifestations of psoriasis or reactive arthritis if the patient has psoriatic skin lesions or has conjunctivitis, urethritis, arthritis, and skin involvement suggestive of reactive arthritis (see Chapter 155, Reactive Arthritis).

TYPICAL DISTRIBUTION

- The lesions are typically found on the anterior two-thirds of the dorsal tongue mucosa.
- Geographic tongue usually affects the tongue, although other oral sites may be involved such as the buccal mucosa, the labial mucosa, and, less frequently, the soft palate.³

DIFFERENTIAL DIAGNOSIS

- Erythroplakia or leukoplakia—May be suspected when lesions affect the soft palate (see Chapter 42, Leukoplakia).
- Lichen planus—Reticular forms are characterized by interlacing white lines commonly found on the buccal mucosa, or erosive forms, characterized by atrophic erythematous areas with central ulceration and surrounding radiating striae (see Chapter 154, Lichen Planus) (**Figure 38-3**).
- Psoriasis—Intraoral lesions have been described as red or white plaques associated with the activity of cutaneous lesions (see Chapter 152, Psoriasis) (**Figure 38-4**).
- Reactive arthritis—A condition characterized by the triad of “urethritis, arthritis, and conjunctivitis,” may have rare intraoral lesions described as painless ulcerative papules on the buccal mucosa and palate (see Chapter 155, Reactive Arthritis).
- Fissured tongue—An inherited condition in which the tongue has fissures that are asymptomatic. Although it has been called a *scrotal tongue* in the past, the term *fissured tongue* is preferred by patients (**Figure 38-5**).

FIGURE 38-2 Geographic tongue lesions in a 71-year-old woman. Note the white halos around the pink areas of atrophy of filiform papillae. (Courtesy of Michael Huber, DMD.)

FIGURE 38-3 Lichen planus of the tongue. There are white striae; the surface is smooth in the affected area because of the loss of papillae. (Courtesy of Richard P. Usatine, MD.)

MANAGEMENT

Most individuals are asymptomatic and do not require treatment (Figure 38-6).

- For symptomatic cases, several treatments have been proposed but not proven effective with good clinical trials:^{6,7}
 - Topical steroids such as triamcinolone dental paste (Oralone or Kenalog in Orabase). **SOR C**
 - Supplements such as zinc, vitamin B₁₂, niacin, and riboflavin. **SOR C**
 - Antihistamine mouth rinses (e.g., diphenhydramine elixir 12.5 mg per 5 mL diluted in a 1:4 ratio with water). **SOR C**
 - Topical anesthetic rinses.^{6,7} **SOR C**

Geographic tongue can rarely present as persistent and painful (Figure 38-7). In one case report, 0.1% tacrolimus ointment was applied twice daily for 2 weeks with significant improvement of symptoms.⁸ **SOR C**

No treatment has been proven to be uniformly effective.⁹

FOLLOW-UP

Tell the patient to contact you if the symptoms continue past 10 days and to go to the emergency department immediately if:

- The tongue swells significantly;
- The patient has trouble breathing; or
- The patient has trouble talking or chewing/swallowing.

PATIENT EDUCATION

Patients should be reassured of the conditions benign nature. Tell patients with geographic tongue to avoid irritating spicy foods and liquids.

39 GINGIVITIS AND PERIODONTAL DISEASE

Richard P. Usatine, MD
Wanda C. Gonsalves, MD

PATIENT STORY

A 35-year-old woman presents to clinic for a routine physical examination. She says that for the last 6 months her gums bleed when she brushes her teeth. She reports smoking 1 pack of cigarettes per day. The oral examination finds generalized plaque and red swollen intradental papilla (**Figure 39-1**). The physician explains to her that she has gingivitis and that she should brush twice daily and use floss daily. The physician tells her that smoking is terrible for her health in all ways, including her oral health. The physician offers her help to quit smoking and refers her to a dentist for a cleaning and full dental examination.

INTRODUCTION

Gingivitis is the inflammation of the gingiva (gums). Gingivitis alone does not affect the underlying supporting structures of the teeth and is reversible (**Figure 39-1**).

Periodontitis (periodontal disease) is a chronic inflammatory disease, which includes gingivitis along with loss of connective tissue and bone support for the teeth. It damages alveolar bone (the bone of the jaw in which the roots of the teeth are connected) and the periodontal ligaments that hold the roots in place. It is a major cause of tooth loss in adults (**Figures 39-2 to 39-4**).

EPIDEMIOLOGY

- Gingivitis and periodontal diseases are the most common oral diseases in adults.
- It is estimated that 35% of adults 30 years of age or older in the United States have periodontal disease: 22% have a severe form and 13% have a moderate-to-severe form.¹
- Homeless persons are a very high-risk group for gingivitis, periodontitis, and all dental disease (**Figure 39-4**).
- Periodontal disease has been shown in some studies to be an associated factor in coronary heart disease and chronic kidney disease.²
- Periodontal disease in pregnancy is associated with an increase in preterm birth.^{3,4}

ETIOLOGY AND PATHOPHYSIOLOGY

- Periodontal diseases are caused by bacteria in dental plaque that create an inflammatory response in gingival tissues (gingivitis) or in the soft tissue and bone supporting the teeth (periodontitis).

FIGURE 39-1 Chronic gingivitis in which the intradental papillae are edematous and blunted. There is some loss of gingival tissue. The gums bleed with brushing. (Reproduced with permission from Gerald Ferretti, DMD.)

FIGURE 39-2 Healthy periodontal anatomy versus periodontal disease. (Reproduced with permission from the American Academy of Periodontology; <http://www.perio.org/consumer/2a.html>.)

- The normal healthy gingival attachments form the gingival cuff around the tooth to help protect the underlying bone and teeth from the bacteria of the mouth.
- Gingivitis is caused by a reversible inflammatory process that occurs as the result of prolonged exposure of the gingival tissues to plaque and tartar (**Figure 39-2**).
- Gingivitis may be classified by appearance (e.g., ulcerative, hemorrhagic), etiology (e.g., drugs, hormones), duration (e.g., acute, chronic), or by quality (e.g., mild, moderate, or severe).
- A severe form, acute necrotizing ulcerative gingivitis (ANUG) (**Figure 39-5**), also known as Vincent disease or trench mouth, is associated with α -hemolytic streptococci, anaerobic fusiform bacteria, and nontreponemal oral spirochetes. The term *trench mouth* was coined in World War I when ANUG was common among soldiers in the trenches. Predisposing factors now include diabetes, HIV, and chemotherapy.²
- The most common form of gingivitis is chronic gingivitis induced by plaque (**Figure 39-1**). This type of gingivitis occurs in half of the population 4 years of age or older. The inflammation worsens as mineralized plaque forms calculus (tartar) at and below the gum surface (sulcus). The plaque that covers calculus causes destruction of bone (an irreversible condition) and loose teeth, which result in tooth mobility and tooth loss.
- Gingivitis may persist for months or years without progressing to periodontitis. This suggests that host susceptibility plays an important role in the development of periodontal disease.⁵

RISK FACTORS

Risk factors that contribute to the development of periodontal disease include poor oral hygiene, smoking, alcohol dependence, environmental factors (e.g., crowded teeth and mouth breathing), and comorbid conditions, such as a weakened immune status (e.g., HIV, steroids, or diabetes), low educational attainment, and low income.⁶⁻⁸

DIAGNOSIS

CLINICAL FEATURES

- Simple or marginal gingivitis first cause swelling of the intradental papillae and later affect the gingiva and dental interface (see **Figures 39-1** to **39-4**).
- Mild gingivitis is painless and may bleed when brushing or eating hard foods.
- ANUG (**Figure 39-5**) is painful, ulcerative, and edematous, and produces halitosis and bleeding gingival tissue. Patients with ANUG may have systemic symptoms such as myalgias and fever.

TYPICAL DISTRIBUTION

Gingivitis begins at the gingival and dental margins and may extend onto the alveolar ridges.

LABORATORY STUDIES AND IMAGING

Radiographs of the mouth are used to evaluate for bone loss in periodontal disease.

FIGURE 39-3 Severe periodontal disease in a woman who smokes and is addicted to cocaine. Note the blunting of the intradental papillae and the dramatic loss of gingival tissue. (Reproduced with permission from Richard P. Usatine, MD.)

FIGURE 39-4 Severe periodontal disease in an alcoholic smoker with very edematous and blunted intradental papilla. This homeless man has already lost two teeth secondary to his severe periodontal disease. (Reproduced with permission from Richard P. Usatine, MD.)

FIGURE 39-5 Acute necrotizing ulcerative gingivitis (ANUG) with intense erythema and ulcerations around the teeth. This is an acute infectious process. (Reproduced with permission from Gerald Ferretti, DMD.)

DIFFERENTIAL DIAGNOSIS

- Gingivitis can be from poor dental hygiene only or secondary to conditions that affect the immune system such as diabetes, Addison disease, HIV, and pregnancy.
- Gingival hyperplasia is an overgrowth of the gingiva with various etiologies, including medications such as calcium channel blockers, phenytoin, and cyclosporine. This can occur with or without coexisting gingivitis (see Chapter 40, Gingival Hyperplasia).

MANAGEMENT

- Recommend smoking cessation for all patients who smoke.⁷ **SOR A** Offer help to support the patients' smoking cessation efforts with behavioral counseling and pharmacologic methods (see Chapter 236, Tobacco Addiction). **SOR A**
- Recommend alcohol cessation for patients with alcoholism and refer to Alcoholics Anonymous (AA) or another resource. For patients in whom alcohol use is heavy but addiction has not been diagnosed, at least recommend a decrease in alcohol use (see Chapter 237, Alcoholism).⁸ **SOR B**
- Dental experts recommend tooth brushing twice a day and flossing daily. **SOR C** However, a Cochrane systematic review failed to show a benefit for daily flossing on plaque and clinical parameters of gingivitis.⁹ **SOR A**
- Some experts suggest that electric toothbrushes may have additional benefit over manual brushing, but this remains unproven. **SOR C** In fact, one study of dental students showed that one electric toothbrush was no better than two different manual toothbrushes with respect to plaque control.¹⁰ **SOR B**
- Systematic reviews indicate that there is strong evidence supporting the efficacy of chlorhexidine as an antiplaque, antigingivitis mouthrinse.¹¹ **SOR A** Mouthwashes should not be used as a replacement for tooth brushing. Chlorhexidine oropharyngeal 0.12% is available as a generic mouthrinse. Recommended dosing is 15 mL to swish (for 30 seconds) and spit twice daily.
- The treatments with chlorhexidine (gel and spray) achieved a significant reduction in plaque and gingival bleeding in children with special needs. The parents/caregivers preferred the administration of chlorhexidine in spray form.¹² **SOR B**
- In patients with ANUG, treatment involves antibiotics, NSAIDs, and topical 2% viscous lidocaine for pain relief. Oral rinses with saline, hydrogen peroxide 3% solution, or chlorhexidine 0.12% may be of benefit. **SOR C**
- Antibiotics recommended for ANUG include penicillin VK, erythromycin, doxycycline, and clindamycin. **SOR C**
- Everyone should receive ongoing care from a dental professional for prevention and treatment of periodontal disease.

PREVENTION

- No smoking or tobacco use at all.
- Avoid alcohol and drug abuse.

- Good oral hygiene with tooth brushing and flossing.
- Dental visits at least twice yearly even during pregnancy.

PATIENT EDUCATION

- There is no safe level of smoking. Quitting is crucial to good health.
- Drink alcohol in moderation or not at all.
- Practice good oral hygiene to remove plaque (i.e., brush twice a day and use floss daily).
- Consider use of chlorhexidine-containing mouthrinse.
- Consult a dentist for regular check-ups, especially when the condition does not improve after using good oral hygiene.
- Pregnancy is not a contraindication for dental visits and cleaning.

FOLLOW-UP

Follow up patients with ANUG closely. All patients need regular dental care and follow-up with their dentist.

40 GINGIVAL OVERGROWTH

Richard P. Usatine, MD
Wanda C. Gonsalves, MD

PATIENT STORY

A 31-year-old woman with a history of seizure disorder notices increasing gum enlargement (**Figure 40-1**). She is unemployed and does not have dental insurance. She has not been to a dentist in at least 10 years. She brushes her teeth only once a day and does not floss at all. She has been on phenytoin (Dilantin) since early childhood, and this does prevent her seizures. You talk to her about dental hygiene and refer her to a low-cost dental clinic that cares for persons with limited resources.

INTRODUCTION

Gingival overgrowth (hyperplasia) can be hereditary or induced as a side effect of systemic drugs, such as phenytoin, cyclosporine, or calcium channel blockers. Besides the cosmetic effect it can make good oral hygiene more difficult to maintain.

SYNONYMS

Gingival hyperplasia, drug-induced gingival overgrowth (DIGO), hereditary gingival fibromatosis.

EPIDEMIOLOGY

- The prevalence of phenytoin-induced gingival hyperplasia is estimated at 15% to 50% in patients taking the medication^{1,2} (**Figures 40-1** and **40-2**).
- In patients receiving cyclosporine for more than 3 months, the incidence of gingival overgrowth (GO) can approach 70%³ (**Figure 40-3**).
- The incidence of gingival hyperplasia has been reported as 10% to 20% in patients treated with calcium channel blockers in the general population.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Although the etiology of GO is not entirely known, risk factors known to contribute to GO include the following: nonspecific chronic inflammation associated with poor hygiene, hormonal changes (pregnancy), medications (calcium channel blockers, phenytoin, and cyclosporine), and systemic diseases (leukemia, sarcoidosis, and Crohn disease).
 - Studies suggest that phenytoin, cyclosporine, and nifedipine interact with epithelial keratinocytes, fibroblasts, and collagen to lead to an overgrowth of gingival tissue in susceptible individuals.²

FIGURE 40-1 Gingival overgrowth secondary to phenytoin (Dilantin) in a woman with epilepsy. (Courtesy of Richard P. Usatine, MD.)

FIGURE 40-2 Multiple tiny hamartomas on the gums from Cowden disease with gingival overgrowth secondary to phenytoin. (Courtesy of Richard P. Usatine, MD.)

- More than 15 drugs have been shown to cause GO.
- The most common nonreversible DIGO is caused by phenytoin (Figures 40-1 and 40-2).
- Histopathologically, tissue enlargement is the result of proliferation of fibroblasts, collagen, and chronic inflammatory cells.

RISK FACTORS

- Prolonged use of phenytoin, cyclosporine, or calcium-channel blockers (especially nifedipine).
- Pregnancy.
- Systemic diseases (leukemia, sarcoidosis, and Crohn disease).
- Poor oral hygiene and the presence of periodontal disease.

DIAGNOSIS

SIGNS AND SYMPTOMS

- The diagnosis is made by visual inspection and by obtaining a thorough history (Figures 40-1 to 40-3).
- The gingiva appears edematous and bulky with loss of its stippling. It may be soft or firm.
- Nonspecific chronic inflammation, hormonal and systemic causes such as leukemia appear red and inflamed and may bleed.

TYPICAL DISTRIBUTION

Lobular gingiva enlargement occurs first at the interdental papillae and anterior facial gingiva approximately 2 to 3 months after starting the drug, and increases in maximum severity in 12 to 18 months (Figure 40-3).

LABORATORY TESTS

Consider checking a complete blood count (CBC) with differential count to investigate for leukemia if there is not an obvious etiology.

IMAGING

The periodontist or oral medicine specialist may order bitewing radiographs and periapical films to evaluate for the presence of periodontal disease.

DIFFERENTIAL DIAGNOSIS

- Generalized gingivitis—Gums around the teeth become inflamed. This condition often occurs with poor oral hygiene (see Chapter 39, Gingivitis and Periodontal Disease).
- Pregnancy gingivitis—Inflamed gums. More than half of pregnant women will develop gingivitis during pregnancy because of hormonal changes.
- Pyogenic granuloma—A small red bump that may bleed and grow to approximately half an inch. These are most often found on the skin but can occur in the mouth secondary to trauma or pregnancy. When they occur in pregnancy, they are sometimes called a pregnancy

FIGURE 40-3 Gingival overgrowth secondary to cyclosporine use for 1 year to treat severe plaque psoriasis. Note the blunted and thickened interdental papillae. (Courtesy of Richard P. Usatine, MD.)

FIGURE 40-4 Pyogenic granuloma growing rapidly on the gums after minor trauma. (Reprinted with permission from Gonsalves WC, Chi AC, Neville BW. *Common oral lesions: part II. Masses and neoplasia.* *Am Fam Physician.* 2007;75(4):509-512. Copyright © 2007 American Academy of Family Physicians. All Rights Reserved.)

tumor. In reality, these are not pyogenic nor granulomatous but are a type of lobular capillary hemangioma (see Chapter 161, Pyogenic Granuloma) (**Figure 40-4**).

- Leukemia—Leukemic cells may infiltrate the oral soft tissues producing a diffuse, boggy, nontender swelling of the gingiva that may ulcerate or bleed.

MANAGEMENT

NONPHARMACOLOGIC

- Teach and emphasize good oral hygiene including cleanings at least every 3 months to control plaque. **SOR C**
- The use of a powered toothbrush, together with oral hygiene instruction, reduces GO for pediatric transplantation patients on cyclosporine. In one study, the sonic toothbrushing and oral hygiene instruction group had less severe GO after 12 months than did the control group.⁴ **SOR B**
- If possible, stop drugs that induce gingival hyperplasia as discontinuing the medications may reverse the condition in most cases (except phenytoin).
- If drugs cannot be stopped, try reducing the dose, if possible, as gingival hyperplasia can be dose dependent.

MEDICATIONS

- Tacrolimus is an alternative to cyclosporine to prevent transplant rejection; it causes less GO. In one study on the prevalence of gingival growth after renal transplantation, GO occurred in 29% of patients treated with tacrolimus and in 60% of patients treated with cyclosporine.⁵ **SOR B** In another study, switching patients from cyclosporine to tacrolimus reduced GO in the first month after the change was made.⁶ **SOR B**
- Case reports have reported regression of overgrowth with both oral metronidazole and azithromycin. In one randomized controlled trial (RCT), patients with GO were randomized to receive either 1 course of 5 days of azithromycin or 7 days of metronidazole. The extent of GO was measured at 0, 2, 4, 6, 12, and 24 weeks, and azithromycin was found to be more effective than metronidazole.³ **SOR B**
- Azithromycin with an oral hygiene program resulted in a reduction in cyclosporine-induced GO, whereas oral hygiene alone improved oral symptoms (pain, halitosis, and gum bleeding) but did not decrease cyclosporine-induced GO.⁷ Patients were randomized into 2 groups, both receiving oral hygiene instructions, with the treatment group receiving 3 days of azithromycin 500 mg daily. They were evaluated after 15 and 30 days and only the azithromycin group had a reduction in GO.⁷ **SOR B**
- Chlorhexidine 12% (Peridex) once before going to bed or Biotene mouthwash after meals is recommended for patients who are known to be at risk for gingivitis.² **SOR C** Warn patients that chlorhexidine 12% will taste bad and can stain the teeth. This staining can be removed with a dental cleaning. This information should help improve adherence to the use of this mouthwash.

REFERRAL

- For patients who do not respond to the above measures, refer to a dental health professional for possible gingivectomy. This can be done with a scalpel or a laser.

PREVENTION

Ensure healthy periodontal tissue prior to starting calcium channel blockers or phenytoin, or before any organ transplantation in which cyclosporine will be prescribed.

Folic acid supplementation, 0.5 mg per day, is associated with prevention of GO in children taking phenytoin monotherapy. Of patients in the folic acid arm, 21% developed GO, as compared with 88% receiving placebo.¹ **SOR B**

PATIENT EDUCATION

Advise patients to practice good oral hygiene (i.e., brush at least twice a day and floss at least once a day) and have regular follow-up with their dental health professional to monitor for worsening periodontal disease.

FOLLOW-UP

- Patients should be monitored by a periodontist or an oral medicine specialist as long as the patients are taking medicines that induce gingival hyperplasia.

41 APHTHOUS ULCER

Richard P. Usatine, MD
Wanda C. Gonsalves, MD

PATIENT STORY

A 58-year-old man presents with a 1-year history of painful sores in his mouth. (Figures 41-1 to 41-4). He has lost 20 pounds over the past year because it hurts to eat. The ulcers come and go, but are found on his tongue, gums, buccal mucosa, and inner lips. Prior to the onset of these lesions the patient had been in good health and was not on any medications. The physician recognized his condition as recurrent aphthous ulcers with giant ulcers. No underlying systemic diseases were found on work-up. The patient was started on oral prednisone and given dexamethasone oral elixir to swish and swallow. Within 1 week the patient was able to eat and drink liquids comfortably and began regaining his lost weight. Long-term management of his problem required the use of other medications so as to successfully taper him off prednisone without recurrences.

INTRODUCTION

Aphthous ulcers are painful ulcerations in the mouth which can be single, multiple, occasional, or recurrent. These ulcers can be small or large but are uniformly painful and may interfere with eating, speaking, and swallowing. Oral trauma, stress, and systemic diseases can contribute to the occurrence of these ulcers but no precise etiology is apparent. Recurrent aphthous stomatitis (RAS) is a frustrating condition that merits aggressive treatment aimed at pain relief and prevention.

SYNONYMS

Canker sores, recurrent aphthous ulcer (RAU), aphthous stomatitis, RAS.

EPIDEMIOLOGY

- Incidence rates of RAUs of 0.85% among adults and 1.5% among children and adolescents have been reported.¹
- RAS is more common in women, in people younger than age 40 years, in whites, in nonsmokers, and in people of high socioeconomic status.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- The precise etiology and pathogenesis of this condition remains unknown, although a variety of host and environmental factors have been implicated.

FIGURE 41-1 Major aphthous ulcer on the buccal mucosa of a 58-year-old man who has been suffering with recurrent aphthous stomatitis for the past year. (Courtesy of Richard P. Usatine, MD.)

FIGURE 41-2 Two aphthous ulcers on the tongue of a 58-year-old man with recurrent aphthous stomatitis. (Courtesy of Richard P. Usatine, MD.)

- A positive family history is seen in about one-third of RAU patients. A genetic predisposition is suggested by an increased frequency of HLA types A2, A11, B12, and DR2.¹
- In one study, Th1 (T-helper subtype 1) activation was more intense in the patients with RAUs. Many conditions that increase the incidence of RAUs, such as psychologic stress, NSAIDs, Crohn disease, and celiac disease, also shift the immune response toward the Th1 subtype. Conditions and medications that inhibit the Th1 immune response pathway, such as pregnancy, thalidomide, glucocorticoids, and tetracycline, decrease the incidence of RAUs.²
- Another study found significantly higher-than-normal serum level of tumor necrosis factor (TNF)- α in 20% to 39% of patients in the ulcerative stage of RAUs.³ Medications that have anti-TNF- α effects, such as pentoxifylline, levamisole, and thalidomide, have also been found to be useful in the treatment of RAUs.¹⁻³
- Although studies show that there are active immune mechanisms associated with RAUs, there is still much to learn regarding their etiology and pathogenesis.

RISK FACTORS

- Oral trauma.
- Stress and anxiety.
- Systemic diseases (celiac disease, Crohn disease, Behçet syndrome, HIV, reactive arthritis).
- Medications (NSAIDs, β -blockers, angiotensin-converting enzyme inhibitors [ACEIs]).
- Vitamin deficiencies (zinc, iron, B₁₂, folate).
- Food and chemical sensitivities.

DIAGNOSIS

CLINICAL FEATURES

History:

- Symptoms may begin with a burning sensation and the pain is exacerbated by moving the area affected by the ulcer.
- Eating often hurts, especially foods and drinks with a high acid content.
- Ask about recurrences and onset in relation to the use of medications.
- Ask about GI symptoms, genital ulcers, HIV risk factors, and joint pain.

Physical:

- Three clinical variations are described based on the size of the ulcers: Minor (4 to 9 mm), major (>1 cm), and herpetiform (<3 mm). The most common minor form appears as rounded, well-demarcated, single or multiple ulcers less than 1 cm in diameter that usually heal in 10 to 14 days without scarring (**Figure 41-5**).
- The ulcers are solitary or multiple covered by a white-to-yellow pseudomembrane and surrounded by an erythematous halo (**Figure 41-5**).

FIGURE 41-3 Minor aphthous ulcer occurring simultaneously with major aphthous ulcers on the buccal mucosa and tongue of a 58-year-old man with recurrent aphthous ulcers. (Courtesy of Richard P. Usatine, MD.)

FIGURE 41-4 Aphthous ulcer located on unkeratinized (movable) mucosa in a 5-year-old girl. It is slightly raised, round, with a white-yellow necrotic center and surrounding erythema. (Courtesy of Richard P. Usatine, MD.)

FIGURE 41-5 Behçet disease characterized by recurrent oral and genital ulcers in a 17-year-old girl. (Courtesy of Richard P. Usatine, MD.)

TYPICAL DISTRIBUTION

RAS usually involves nonkeratinizing mucosa (e.g., labial mucosa, buccal mucosa, ventral tongue). Aphthous ulcers spare the attached gingiva and the hard palate (nonmovable mucosa).

LABORATORY TESTS

Consider complete blood count (CBC), ferritin, B₁₂, folate, erythrocyte sedimentation rate (ESR), viral culture, KOH, skin biopsy, and HIV testing, if indicated.

DIFFERENTIAL DIAGNOSIS

- Primary oral herpes simplex virus (primary gingivostomatitis)—Begins as vesicular lesions, which quickly ulcerate on all mucosal lesions in the mouth. It is accompanied by systemic manifestations such as fever, malaise, anorexia, and sore throat. The ulcers are located on movable and nonmovable oral mucosa (includes attached gingiva and hard palate). Lesions may also appear on keratinized surfaces such as the lip (see Chapter 129, Herpes Simplex).
- Herpangina causes multiple ulcers in the mouth, especially on the soft palate and the anterior fauces. It is caused by coxsackievirus A16 in most cases. The distribution of the ulcers is different than in aphthous ulcers.
- Candidiasis—White plaque, when removed, appears red. Scrape white plaque and a KOH preparation will be positive for yeast. (see Chapter 136, Candidiasis).
- Oral cancer—Ulcerative lesion that will not resolve by 2 weeks (see Chapter 43, Oral Cancer).
- Erythema multiforme (EM)—Mucocutaneous lesion preceded by infection of herpes simplex virus (HSV), *Mycoplasma pneumoniae*, or exposure to certain drugs or medications. Oral lesions begin as patches and evolve into large shallow erosions and ulcerations with irregular borders. Common sites include the lip, tongue, buccal mucosa, floor of the mouth, and soft palate. The presence of targetoid skin lesions should help differentiate EM from RAS (see Chapter 177, Erythema Multiforme, Stevens-Johnson Syndrome, and Toxic Epidermal Necrolysis).
- Erosive lichen planus—Erythematous ulcerative lesion with surrounding striae (see Chapter 154, Lichen Planus).
- Behçet syndrome—A condition with multiple ulcerative lesions that resemble aphthae involving the soft palate and oropharynx, infrequent sites for routine aphthae. Common cutaneous lesions include the genital and ocular mucosa (**Figure 41-6**).
- Hand, foot, and mouth disease presents as mucocutaneous lesions involving the hand, foot, and mouth caused by enterovirus. Any area of mucosa may be involved. Lesions resolve within 1 week (see Chapter 128, Hand, Foot, and Mouth Disease).

MANAGEMENT**NONPHARMACOLOGIC**

- Most isolated aphthae require no treatment or only periodic topical therapy.

FIGURE 41-6 Ulcer on penis in a patient with Behçet Syndrome. (Courtesy of Richard P. Usatine, MD.)

MEDICATIONS

Topical corticosteroids, such as fluocinonide gel or dexamethasone elixir, can promote healing and lessen the severity of RAS.⁴ Patients should be instructed to dab the area of ulcer dry, apply the gel, paste, or cream after rinsing, and avoid eating or drinking for at least 30 minutes. **SOR C**

- Amlexanox 5% paste (Aphthasol) reduces ulcer size, pain duration, and healing time.⁵ It is nonprescription and the paste is applied directly to ulcers four times a day until ulcers heal.⁵ **SOR B**
- Lidocaine 1% cream applied to aphthous ulcers was found to reduce pain intensity compared to the placebo cream.⁶ **SOR B**

In severe RAS cases, systemic therapy with oral steroids, montelukast, colchicine, pentoxifylline, azathioprine, clofazimine, or thalidomide may need to be considered:

- Both prednisone and montelukast were effective in reducing the number of aphthous ulcers and improving pain relief and ulcer healing when compared with placebo in a randomized controlled trial (RCT).⁷ Prednisone was more effective than montelukast in pain cessation ($P < 0.0001$) and in accelerating ulcer healing ($P < 0.0001$). Montelukast may be useful in cases of RAS where pharmacologic therapy for long periods is needed and prednisone is to be avoided.⁷ In this study, prednisone was given 25 mg daily for 15 days, 12.5 mg daily for 15 days, 6.25 mg daily for 15 days, and then 6.25 mg on alternate days for 15 days. Montelukast 10 mg daily was given every evening and then on alternate days for the second month.⁷ **SOR B**
- In one RCT, 5 mg per day prednisolone was compared with 0.5 mg per day colchicine in the treatment of RAS. Both colchicine and prednisolone treatments significantly reduced RAS. No significant differences in size and number of lesions, recurrence and severity of pain, and duration of pain-free period were seen between the two treatment groups. Colchicine (52.9%) had significantly more side effects than prednisolone (11.8%), so the prednisolone seems to be a better alternative in reducing the signs and symptoms of RAS.⁸ **SOR B**
- Clofazimine 100 mg daily for 30 days and then 100 mg every other day has been studied in a partially blinded RCT for the prevention of RAS. A greater percentage of individuals in the clofazimine group had no further aphthous episodes (17% to 44%) compared with the other groups (<6%).⁹
- A multicenter cohort analysis of thalidomide for severe RAS was recently published. The authors conclude that low-dose maintenance regimens of thalidomide appear to be effective, and relatively well tolerated. However, adverse events were reported by 84% (77 of 92) of patients. If thalidomide is needed, refer the patient to a specialist with experience using this toxic drug.¹⁰ **SOR B**

COMPLEMENTARY AND ALTERNATIVE THERAPY

Vitamin C was shown to reduce the frequency of minor RAS and the severity of pain by 50% in a small group of teens. They were given 2000 mg/m² per day of ascorbate.¹¹

REFERRAL

Consider referring children with periodic fever with aphthous stomatitis, pharyngitis, and adenitis (PFAPA) syndrome for tonsillectomy

or adenotonsillectomy. A metaanalysis found little evidence to support surgery, but the authors concluded that surgery is an option when symptoms markedly interfere with the child's quality of life and medical treatment has failed.¹² **SOR C**

PREVENTION

Oral vitamin B₁₂ was studied in a RCT of primary care patients. A sublingual dose of 1000 mcg of vitamin B₁₂ was used by patients in the intervention group for 6 months. During the last month of treatment more participants in the intervention group reached a status of "no aphthous ulcers" (74.1% vs. 32.0%; P < 0.01). The treatment worked regardless of the serum vitamin B₁₂ level.¹³ **SOR B**

See data on clofazimine and thalidomide under "Medications" above.

PATIENT EDUCATION

Recurrent lesions that do not respond to treatment and severe cases should be seen by their oral health provider or primary care physician to look for an underlying cause. Foods that are spicy or acidic worsen pain and should be avoided.

42 LEUKOPLAKIA

Michael A. Huber, DDS
Wanda C. Gonsalves, MD

PATIENT STORY

A 57-year-old male smoker presents at the physician's clinic with a 7-month history of a nonpainful white patch below his tongue. He admits to drinking 2 to 3 beers in the evening and smoking 1 pack of cigarettes per day. Your examination reveals a painless white, thick lesion with fissuring below the tongue (**Figure 42-1**). A biopsy shows this to be premalignant and the patient is told that he must stop smoking and drinking. He is also referred to an oral surgeon for further evaluation of his dysplasia.

INTRODUCTION

The World Health Organization defines leukoplakia as a clinical term used to recognize “white plaques of questionable risk having excluded (other) known diseases or disorders that carry no increased risk for cancer.”^{1,2} For all types of leukoplakia (see “Clinical Features” below) the risk of malignant transformation is approximately 1%, with a much higher risk associated with leukoplakias manifesting a red and/or highly variable surface texture component.

The term *erythroplakia* is reserved for a purely red lesion, which is described as a “fiery red patch that cannot be characterized clinically or pathologically as any other definable disease.”^{1,2} It may be flat or slightly depressed and exhibits a smooth or granular surface texture. The majority of erythroplakias will undergo malignant transformation.

SYNONYMS

Homogenous leukoplakia; nonhomogenous leukoplakia; speckled leukoplakia; nodular leukoplakia; verrucous leukoplakia; erythroleukoplakia; erythroplakia; erythroplasia.

EPIDEMIOLOGY

- Leukoplakia occurs in 0.5% to 2.0% of adults and is most frequently seen in middle-age and older men.¹
- Erythroplakia occurs in approximately 0.02% to 0.83% of adults and is most commonly observed in middle-age and elderly persons, with no gender distinction.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- Both leukoplakia and erythroplakia likely represent clinical changes associated with the underlying multistep progression of alterations

FIGURE 42-1 Homogenous leukoplakia on the lateral tongue presenting with a uniform surface plaque and surface cracks in a patient with a long smoking history. A 4-mm punch biopsy was performed and showed moderate dysplasia. (Courtesy of Richard P. Usatine, MD.)

at the molecular level underlying the development of dysplasia and subsequent carcinoma.

- For all types of leukoplakia, the risk of malignant transformation is approximately 1%, with a much higher risk associated with leukoplakias manifesting a red component.¹
- For erythroplakia, the risk of malignant transformation is extremely high, with 85% of cases demonstrating either dysplasia or carcinoma in situ at the time of biopsy.³

RISK FACTORS

- Smoking and alcohol exposure are the most prominent risk factors for leukoplakia and erythroplakia, and create a synergistic effect when combined.¹
- Human papillomavirus (HPV) is a recognized risk factor for oropharyngeal cancer, but its association with leukoplakia and erythroplakia is undetermined.⁴
- Up to 27% of leukoplakias are idiopathic.⁴

DIAGNOSIS

- Both leukoplakia and erythroplakia are clinical working diagnoses of exclusion, to be applied when other conditions have been excluded.

CLINICAL FEATURES

- Leukoplakia may be characterized as either homogenous or non-homogenous.^{1,2}
- Homogenous leukoplakia (**Figure 42-1**) presents uniformly as a thin surface plaque with possible shallow surface cracks.²
- Nonhomogenous leukoplakia (**Figures 42-2** and **42-3**) may be further characterized as speckled (white predominant with interspersed red component); nodular (small polypoid outcrops, may be red or white); or verrucous (corrugated or folded surface appearance).²
- Erythroplakia (**Figure 42-4**) presents as distinct flat or slightly depressed red lesion with a smooth or granular surface texture.^{1,2}

TYPICAL DISTRIBUTION

- Both leukoplakia and erythroplakia may occur on any oropharyngeal mucosal site.⁴
- Lesions affecting the floor of the mouth, ventral/lateral tongue, and possibly the soft palatal complex, are associated with a increased risk for malignant transformation.^{4,5}
- Idiopathic leukoplakias demonstrate a significantly higher risk of malignant transformation compared to risk-associated variants.⁴

LABORATORY

A biopsy is required to determine the histologic characterization of the lesion. Usually a 4-mm punch biopsy is a good start, but be wary of a false negative as a consequence of sampling error. If the lesion appears suspicious, refer to an oral surgeon, even with a negative result.

FIGURE 42-2 Nonhomogenous leukoplakia of the right ventral tongue in a 54-year-old white woman. Although she is a nonsmoker, she did have moderate alcohol exposure. Previous biopsy 6 years ago revealed hyperkeratosis. New biopsy indicated moderate to severe dysplasia. Patient was managed with total excision of the leukoplakia and an AlloDerm graft. (Courtesy of Michael Huber, DDS.)

FIGURE 42-3 Leukoplakia (nonhomogenous) with moderate dysplasia on the lateral border of the tongue of a 65-year-old woman with a long history of smoking. She presented with discomfort and a noticeable white plaque on her tongue; a biopsy proved this to be moderate dysplasia. This was the third white dysplastic lesion she had developed in this area. A new excision will be performed and close follow-up is needed. Even though she quit smoking a few years ago, the damage done has led to a relentless dysplastic process. (Courtesy of Ellen Eisenberg, DMD.)

DIFFERENTIAL DIAGNOSIS^{1,2}

- Aspirin/chemical burn—Determined by history.
- Candidosis—Typically symmetrical and wipes off.
- Discoid lupus—Concurrent cutaneous lesions, circumscribed mucosal lesion with central erythema, radiating white lines, histopathology.
- Hairy leukoplakia—Characteristic clinical presentation (bilateral tongue), histopathologic evidence Epstein-Barr virus (EBV).
- Lichen planus—Presence of striations, symmetrical presentation.
- Lichenoid lesion—Presence of striations, temporal association with trigger agent (e.g., new drug, dental material, home care product).
- Linea alba—Parallel to line of occlusion, often bilateral.
- Morsicatio—Habitual chewing or biting habit of the oral mucosa, often bilateral (**Figure 42-5**).
- Nicotine stomatitis—Smoking habit, characteristic appearance (**Figure 42-6**).
- Snuff patch—Characteristic folded, corrugated appearance at site of tobacco placement.
- White sponge nevus—Familial history, symmetrical pattern, and other mucosal sites often involved.

MANAGEMENT

MEDICATIONS

- There are no pharmacologic regimens to manage either leukoplakia or erythroplakia.

SURGERY

- All leukoplakias and erythroplakias should be excised and biopsied to determine the presence of epithelia dysplasia, carcinoma in situ, or squamous cell carcinoma.^{1,6,7} **SOR C**
- Watchful waiting is not recommended.

REFERRAL

- Refer as appropriate to an oral and maxillofacial surgeon, an oral medicine expert, or an ear, nose, and throat (ENT) surgeon.

PREVENTION AND SCREENING

- Risk reduction measures are to be encouraged.
- Ensure a thorough and disciplined soft-tissue examination is accomplished on a routine basis.

PROGNOSIS

- Highly variable for leukoplakia; it may ultimately regress and disappear, persist, or progress to eventual carcinoma. Leukoplakia may recur after excision.⁶⁻⁸
- Erythroplakia almost always progresses to cancer.^{1,3}

FIGURE 42-4 Erythroplakia with red patch (arrow) on the upper alveolar ridge of an edentulous person. (Courtesy of Gerald Ferritti, DMD.)

FIGURE 42-5 Morsicatio—leukoplakia caused by habitual chewing and biting of the oral mucosa. This young man only reluctantly acknowledged this habit upon further questioning of his bilateral leukoplakia. (Courtesy of Richard P. Usatine, MD.)

FIGURE 42-6 Nicotine stomatitis is observed in smokers. Note the hyperkeratosis affecting the hard palate and the erythematous minor salivary duct orifices. (Courtesy of Michael Huber, DDS.)

FOLLOW-UP

- Routine monitoring (e.g., every 3 to 6 months) for recurrence should be done.⁶⁻⁸ **SOR C**
- Risk factor elimination may reduce the risk of recurrence.^{1,6,9}

PATIENT EDUCATION

- Counsel patients who use tobacco (e.g., smoke or smokeless tobacco) to quit. Ask if they are ready to quit at each visit, and sign a contract with them that specifies the date and time they will quit. Provide tools (see “Patient Resources” below) they can use to quit (see Chapter 236, Tobacco Addiction).

43 OROPHARYNGEAL CANCER

Michaell A. Huber, DDS
Wanda C. Gonsalves, MD

PATIENT STORY

A 66-year-old man presents to the physician's office with a nonhealing painful lesion on the roof of his mouth (**Figure 43-1**). The lesion has increased in size recently and he is worried because his dad died from oral cancer. Your patient has smoked since he was 11 years old by getting cigarettes from his dad. He admits to being a heavy drinker. A biopsy shows squamous cell carcinoma and the patient is referred to a head and neck surgeon.

INTRODUCTION

In spite of the relative ease for the healthcare provider to accomplish a visual and tactile examination of the oropharyngeal cavity, fully two-thirds of oropharyngeal cancers (OPCs) will present with advanced disease at the time of diagnosis.¹ Ninety percent of OPCs are of the squamous cell type. Concern has been raised that practitioners are missing early disease by not accomplishing a thorough soft-tissue examination on a routine basis.² However, the fact that more than 35% of patients do not see a dentist on a routine basis likely contributes to the diagnostic delay.³ The 5-year survival rate is 62% for whites and 42% for blacks.¹

SYNONYMS

Oral cancer; oral squamous cell carcinoma; mouth cancer; site specific (e.g., gingival cancer, tongue cancer, lip cancer).

EPIDEMIOLOGY

- In the United States, an estimated 40,000 OPC cases occur annually, accounting for approximately 3.3% of malignancies among men and 1.5% of malignancies among women.¹
- The median age at diagnosis is 62 years and more than 70% of cases occur after the age of 55 years.⁴
- Incidence rates vary from a low of 3.9 per 100,000 Hispanic women to a high of 16.1 per 100,000 white men.⁴
- Up to 35% of OPC patients will develop a new primary tumor within 5 years.⁵

ETIOLOGY AND PATHOPHYSIOLOGY

- Typical OPC develops from a complex multistep progression marked by alterations at the molecular level, followed by

FIGURE 43-1 Squamous cell carcinoma of the palate of a 66-year-old man who smokes and drinks. (Courtesy of Frank Miller, MD.)

phenotypic changes and subsequent clinically observable changes affecting the squamous epithelium.⁶

RISK FACTORS

- Tobacco use is the major risk factor for OPC and is implicated in approximately 75% of cases.⁷
- Alcohol use is a major risk factor and the combined use of tobacco and alcohol increases the risk of OPC far more than either alone.⁷
- Human papillomavirus (HPV) (especially HPV 16) is a newly recognized major risk factor for carcinomas affecting the lingual and palatine tonsils.⁸
- Other risk factors include betel quid chewing, low intake of fruits and vegetables, immunosuppression, and maté drinking.⁹
- Excess sun exposure is the major risk factor for cancer of the lip.⁷

DIAGNOSIS

- A scalpel biopsy is required to establish the diagnosis.^{5,10}

CLINICAL FEATURES

- OPC may affect any area of the oropharyngeal cavity.
- Early OPC often presents as a leukoplakia or erythroplakia (**Figure 43-1**). High-risk sites are the floor of the mouth and ventrolateral tongue (**Figure 43-2**).
- Features of more advanced disease include induration, persistent ulceration, tissue proliferation or erosion, pain or paresthesia, loss of function, and lymphadenopathy (**Figures 43-3 to 43-5**).¹⁰
- HPV-associated carcinomas are often less visible and share signs and symptoms (e.g., sore throat, hoarseness, earaches, enlarged lymph nodes) of tonsillitis and pharyngitis. More advanced symptoms include dysphagia, hemoptysis, and weight loss.¹⁰
- Lip cancer typically presents as a relapsing or persistent chronic scab, plaque, crust, or ulceration (**Figure 43-6**). Antecedent actinic cheilosis is commonly observed.
- Nonsquamous type cancers (e.g., salivary gland tumors, melanoma, sarcomas) often present as a submucosal nodular swelling or mass (**Figures 43-7 and 43-8**).

TYPICAL DISTRIBUTION

- OPCs occur most commonly (in order of frequency) on the tongue, floor of mouth, and lower lip vermilion. The lymphoepithelial tissues of the Waldeyer ring (lateral tongue extending to the lateral soft palate and tonsillar area) has the greatest risk of developing an HPV-associated OPC.⁸

LABORATORY

- A scalpel biopsy is required to establish the diagnosis. An excisional biopsy is preferred to better ensure all suspicious tissue is available for histologic assessment. Confirmed cases are staged utilizing the TNM (tumor, nodes, metastases) scheme.

FIGURE 43-2 Squamous cell carcinoma on the lateral side of the tongue. This is a broad erythroleukoplakic plaque with surface ulcerations. (Courtesy of Ellen Eisenberg, DMD.)

FIGURE 43-3 Squamous cell carcinoma arising on the buccal mucosa. (Courtesy of Gerald Ferritti, DDS.)

FIGURE 43-4 Exophytic cancer of the mouth. (Courtesy of Gerald Ferritti, DDS.)

DIFFERENTIAL DIAGNOSIS

- OPC is capricious and may initially mimic any number of benign conditions such as aphthae, chronic ulcerative conditions, pharyngitis, and tonsillitis.
- Any lesion deemed suspicious or equivocal at discovery should be referred to an expert (oral and maxillofacial surgeon, an oral medicine expert, or an ear, nose, and throat [ENT] surgeon) for further assessment or immediate biopsy.
- Findings deemed innocuous should be reevaluated within 2 weeks for resolution and referred to an expert for further assessment or undergo biopsy if still present (**Figure 43-9**).

MANAGEMENT

- Confirmed OPC is best managed by the oncology team whose members deliver all indicated therapeutic antitumor modalities and provide appropriate adjunctive services such as dental care and nutritional, psychological, and social support. TNM staging is useful for treatment planning and prognostication.
- The principal therapeutic modalities are surgery, radiotherapy, and chemotherapy.^{11,12}
- The use of one treatment over another depends on the size, location, and stage of the primary tumor, the patient's ability to tolerate treatment, and the patient's desires.^{11,12}
- Surgical excision is the preferred modality for most well-defined and accessible solid tumors; however, it has its limitations for inaccessible or more advanced tumors demonstrating lymph node involvement and/or metastasis.^{11,12}
- Radiotherapy may be either an effective alternative to surgery or a valuable adjunct to surgery and/or chemotherapy in the locoregional treatment of malignant head and neck tumors.^{11,12}
- Protocols utilizing concomitant chemoradiotherapy improve both locoregional control and survival.¹²

PROGNOSIS

- Early OPCs (stage I and stage II) of the lip and oral cavity are highly curable with 5-year survival rates exceeding 90%.¹¹
- Later stage OPCs (stage III and stage IV) have a more guarded prognosis with 5-year survival rates ranging from 23% to 58%.¹

FOLLOW-UP

- Vigilant posttherapy follow-up is required (every 6 months).
- Posttherapy OPC patients are at risk for developing a second primary tumor, 3% to 7% per year.¹²

PATIENT EDUCATION

Advise patients to discontinue smoking and/or drinking alcohol.

FIGURE 43-5 Squamous cell carcinoma manifesting chronic ulceration with induration on the right side of the tongue in a homeless patient. (Courtesy of Richard P. Usatine, MD.)

44 EARLY CHILDHOOD CARIES

Adriana Segura, DDS, MS
Wanda C. Gonsalves, MD

PATIENT STORY

A mother brings her 18-month-old son to the physician's clinic for his well-child examination. He is almost weaned from his bottle, but still drinks from a bottle to go to sleep. During the day, he uses a sippy cup to drink everything—from milk to soda. His mother has started giving him apple juice in the bottle instead of milk because he tends to get constipated. On performing an oral examination, the physician notices that several of his teeth have “white spots” (**Figure 44-1**). The physician discusses dental hygiene and treats him with topical fluoride gel.

INTRODUCTION

Dental caries continues to be the most prevalent chronic disease problem facing infants and children. The American Academy of Pediatric Dentistry, American Academy of Pediatrics, and American Dental Association recommend that a child's first visit to a dentist should occur 6 months after the eruption of the first tooth or at 1 year of age. Providing a dental home by age 1 year allows the health provider to complete a risk assessment, provide an introduction to dentistry, and provide anticipatory guidance. It is important to be able to recognize disease and to provide prevention strategies early on to the parents/caregivers.

SYNONYMS

Nursing bottle caries, baby bottles caries.

EPIDEMIOLOGY

- Early childhood caries (ECC; tooth decay) is the single most common chronic childhood disease. It is 5 times more common than asthma and 7 times more common than hayfever among children 5 to 7 years of age.¹
- Tooth decay affects more than 25% of U.S. children between 2 and 5 years of age and about half of those 12 to 15 years of age.
- Disparities in oral health exist—In 2002, 32% of Mexican American and 27% of non-Hispanic black children 2 to 11 years of age had untreated decay in their primary teeth, compared to 18% of non-Hispanic white children.^{2,3}
- ECC is defined as “the presence of one or more decayed (noncavitated or cavitated lesions), missing (as a consequence of caries), or filled tooth surfaces in any primary tooth in a child 71 months of age or younger (**Figures 44-2 to 44-4**).”⁴

FIGURE 44-1 Demineralization at gingiva margins characterized by whitish discolorations. (Courtesy of Gerald Ferretti, DMD.)

FIGURE 44-2 Central maxillary incisors with severe tooth decay, and bilateral maxillary lateral incisors with demineralized area near gingival line (yellow-brownish discolorations). The upper incisors are often the first teeth involved in nursing bottle caries. (Courtesy of Gerald Ferretti, DMD.)

- Consequences of ECC include poor self-esteem, diminished physical development, decreased ability to learn, higher risk of new caries, and added cost.⁴

ETIOLOGY AND PATHOPHYSIOLOGY

- Dental caries is a multifactorial, infectious, communicable disease caused by the demineralization of tooth enamel (**Figure 44-1**) in the presence of a sugar substrate and acid-forming cariogenic bacteria, *Streptococcus mutans* (also known as *mutans streptococci*), which is considered to be the primary strain causing decay that are found in the soft gelatinous biofilm.
- Caries can develop at any time after tooth eruption. Early teeth are principally susceptible to caries caused by the transmission of *S. mutans* from the mouth of the caregiver or sibling(s) to the mouth of the infant or toddler. This type of tooth decay is called baby bottle tooth decay, nursing bottle caries, or ECC.

RISK FACTORS

Risk factors for caries development include:

- Frequent consumption of liquids.
- Repetitive use of a “sippy cup” containing sugars (juice, milk, formula, soda).
- Consumption of sticky foods.
- Human breast milk is uniquely superior in providing the best possible nutrition to infants and, by itself, has been shown to be noncariogenic.³

Nighttime bottle feeding and caregiver with caries.

- Drinking unfluoridated community water or bottled water, which usually lacks fluoride.
- Low socioeconomic status.
- Taking medications that contain sugar or cause dryness.

Lack of good oral hygiene practices.
Subnormal saliva and function.

DIAGNOSIS

CLINICAL FEATURES

- Demineralized areas develop on the tooth surfaces, between teeth, and on pits and fissures. These areas are painless and appear clinically as opaque or brown spots (**Figure 44-1**). White-spot lesions are the first indication the demineralization has started.
- Infection that is allowed to progress forms a cavity that can spread to and through the dentin (the component of the tooth located below the enamel) and to the pulp (composed of nerves and blood vessels; an infection of the pulp is called pulpitis) causing pain, necrosis, and, perhaps, an abscess.

FIGURE 44-3 Severe ECC in a 4-year-old with severe decay of all four maxillary incisors. (Courtesy of Richard P. Usatine, MD.)

FIGURE 44-4 Severe ECC in a 3-year-old with multiple areas of cavitory lesions involving the mandibular incisors and missing maxillary incisors secondary to decay. (Courtesy of Richard P. Usatine, MD.)

TABLE 44-1 Supplemental Fluoride Dosage Schedule

Age	Concentration of Fluoride in Water		
	<0.3 ppm F	0.3 to 0.6 ppm F	>0.6 ppm F
Birth to 6 months	0	0	0
6 months to 3 years	0.25 mg	0	0
3 to 6 years	0.50 mg	0.25 mg	0
6 to at least 16 years	1.00 mg	0.50 mg	0

Source: *The Guideline on Fluoride Therapy* (2008 revision) is Copyright © 2007-2008 by the American Academy of Pediatric Dentistry and is reproduced with their permission. http://www.aapd.org/media/policies_guidelines/g_fluoridetherapy.pdf.

TYPICAL DISTRIBUTION

Demineralized (white or brown spots) and carious lesions generally occur at the margins of the gingiva upper incisors, and later first and second molars in pits and grooves of occlusal surfaces. Lower incisors are rarely affected.

LABORATORY AND IMAGING

Demineralized lesions may not be seen on radiographs, but advanced carious lesions between and on the occlusal surfaces are detected by X-ray.

MANAGEMENT

- Counsel patients about the importance of good oral hygiene practices and perform a caries risk assessment during well-child examination visits.^{5,6} **SOR B**
- Refer to the dental health professional for the application of pit and fissure sealants.^{5,6} **SOR B**
- Before prescribing supplemental fluoride, the primary care provider must determine the fluoride concentration in the child's primary source of drinking water. If fluoridated water is not available in the community, natural sources of fluoride are well water exposed to fluoride minerals and certain fruits and vegetables grown in soil irrigated with fluoridated water.⁷ **SOR B**
- Fluoride supplementation is not recommended for use by persons who live in communities whose water is optimally fluoridated (0.7 to 1.2 parts per million [ppm] or >0.6 mg/L). See **Table 44-1** for fluoride supplementation.⁷ **SOR A**
- Advise the caregiver to take the child to a dentist by age 1 year.⁶ **SOR C**
- Application of fluoride varnishes twice per year in moderate to high-risk children have been shown to prevent caries in demineralized enamel.⁸ **SOR A**

FOLLOW-UP

Ensure that any child whose teeth has "white spots" or visible caries is taken to a dentist for evaluation and treatment so the teeth can be saved from decay or repaired.

PATIENT EDUCATION⁶

- Give the child's caregiver anticipatory guidance that is appropriate to the child's age and dental development. Before the teeth erupt, the caregiver should use a washcloth or cotton gauze to clean a baby's mouth and to transition the child to tooth brushing. **SOR C**
- A "smear" of fluoridated toothpaste (approximately 0.1 mf fluoride) should be considered for children younger than 2 years of age who are at moderate risk or high risk for caries (**Figure 44-5**).⁶ **SOR B**
- A "pea size" amount of toothpaste (approximately 0.2 mg fluoride) is appropriate for children 2 through 5 years of age.⁶ **SOR B**
- The caregiver should brush the child's teeth until the child is capable of doing an adequate job (usually around age 7 years).
- Educate caregivers about the benefits of fluoride and fluorosis, and the possible side effects of using too much fluoride (see **Table 44-1**).
- Advise caregivers to teach the child to drink from a "sippy cup" as soon as possible and to avoid giving the child milk, juice, or soda in either a bottle or sippy cup when putting the child to bed.

Breastfeeding by itself is noncariogenic but when supplemented with other carbohydrates can place the child at risk for caries.^{9,10}

The American Academy of Pediatric Dentistry (AAPD) promotes breastfeeding for infants but recommends cessation of ad libitum breastfeeding as the first primary tooth begins to erupt and other dietary carbohydrates are introduced.⁹ **SOR C**

45 ADULT DENTAL CARIES

Juanita Lozano-Pineda, DDS, MPH
Wanda C. Gonsalves, MD

PATIENT STORY

A 41-year-old homeless man presents to a clinic on “skid row” with a toothache (**Figure 45-1**). He has a history of alcoholism and smoking. Many of his teeth are loose and a number of his teeth have fallen out in the past year. He acknowledges that he does not floss or brush his teeth regularly. He has been sober for 60 days now and wants help to get his teeth fixed. He states that no one will hire him with his teeth as they are. He also has pain in a molar and wants something for the pain until he can see a dentist. On oral examination, you see missing teeth, generalized plaque, and teeth with multiple brown caries.

INTRODUCTION

Dental caries is a multifactorial disease that is primarily caused by an interaction between bacteria and fermentable carbohydrates producing acid that has potential to demineralize the tooth surface over time. Host factors, such as the plaque (biofilm) adherence, quality and quantity of saliva, immune system response, use of fluoride, and a diet that is caries-promoting, play a role in the formation of incipient demineralized lesions that progress to dental caries. Caries risk is impacted by factors that may be behavioral, biologic, environmental, lifestyle-related, and physical. Age, diabetes, ethnic origin, gingival recession, smoking, and socioeconomic status are frequently associated with high caries prevalence.¹

SYNONYMS

Dental decay, dental cavities, cavitated lesions.

EPIDEMIOLOGY

- Many adults (e.g., 31% of those 20 to 34 years of age, 27% of those 35 to 49 years of age, 24% of those 50 to 64 years of age, and 20% of those 65 years of age and older) have untreated dental caries (**Figure 45-1**).²
- Black and Hispanic adults, younger adults, and those with lower incomes and less education have more untreated decay.³
- Many older adults suffer from root caries (decay on the roots of their teeth) (**Figure 45-2**). The percentage of adults with root caries increased with age: 8% of adults 20 to 39 years of age had root decay, compared with 11% of adults 40 to 59 years of age, and 13% of adults 60 years of age and older. The prevalence is greater for black non-Hispanics (20%) and adults below 100% poverty level (19%).⁴
- More than twice as many current smokers (19%) as nonsmokers (7%) had root caries.⁴

FIGURE 45-1 Severe caries in a homeless man. (Courtesy of Richard P. Usatine, MD.)

FIGURE 45-2 Root caries in a woman with a history of substance abuse. She has lost all of her upper teeth and is beginning to lose her lower teeth. Note the exposed and darkened roots. (Courtesy of Richard P. Usatine, MD.)

ETIOLOGY AND PATHOPHYSIOLOGY

- Dental caries result from the activity of dental bacterial plaque, a complex biofilm containing microorganisms that demineralize and proteolyse tooth enamel and dentin through their action on the fermentation of sucrose and other sugars. The main organism is *Streptococcus mutans*.
- A caries-promoting diet that is high in sugar or acid increases the demineralization process. A cariostatic diet that contains calcium helps buffer the acidity and increase remineralization of the tooth's enamel surface.
- Low saliva flow and low pH also increase demineralization; the lack of saliva to buffer the acidity from plaque and diet increases caries risk.
- Dental caries progression or reversal depends on the balance between demineralization and remineralization. If caries is untreated and progresses, it eventually destroys enough tooth structure to either have the unsupported tooth fracture, or the caries reaches the tooth's pulp (nerve tissue) and leads to infection that can progress through the pulp to the tooth's root apex and surrounding bone.
- Plaque also impacts the gingival tissues; if it is not removed regularly, it may calcify with the minerals in the saliva and form calculus (tartar).

RISK FACTORS

The risk factors for adult caries include:⁵⁻⁷

- Increased acidic environment that may be a result of:
 - A diet that is high in fermentable carbohydrates and/or acid.
 - High quantity of bacteria/poor oral hygiene.
 - Physical and medical disabilities that often prevent proper oral hygiene.
 - Medications that decrease pH.⁶
 - Acid reflux.
 - Bulimia.
- Low saliva flow and dry mouth:
 - Medications that decrease saliva flow (tricyclic antidepressants, antihistamines, steroids, diuretics).
 - Illicit drugs such as methamphetamine and cocaine dry the mouth.
 - Radiation to the head and neck that may damage salivary glands.
 - Sjögren syndrome affects saliva glands and decreases flow rate.
- The presence of existing restorations or oral appliances.
- Gingival recession exposing root surfaces that demineralize at a higher pH.
- Low socioeconomic status with limited or no access to medical or dental care.

DIAGNOSIS

Caries can be diagnosed clinically through visual examination of the teeth, where lesions range from a white spot (incipient) to a large

cavitated lesion. Radiographically, the carious lesion appears radiolucent (as a consequence of demineralization or cavitation) within a radiopaque, calcified tooth structure.

CLINICAL FEATURES

- Dental caries initially present as a painless white spot (demineralization of enamel) and if contributing risk factors are not modified, it progresses to a brownish discoloration, with eventual cavitation into the dentin. Pain is usually not felt until the caries progresses into the dentin and/or approximates the pulp. It presents only when stimulated with cold or sweets, and rarely with heat, subsiding shortly after stimulus removal. Once the caries infects the nerve, it leads to pulpal necrosis. The patient may present with pain that is spontaneous, triggered with heat and lingers, is more severe, and may be accompanied with soft-tissue swelling.

TYPICAL DISTRIBUTION

Any enamel, exposed dentin or cementum surface, including occlusal, interproximal, and root surfaces.

LABORATORY AND IMAGING

An X-ray will show the extent of the cavity, but not all demineralized areas.

DIFFERENTIAL DIAGNOSIS

- Fluorosis—Mild fluorosis may present as white spot lesions with an appearance that is similar to the “white-spot” incipient carious lesions.
- Dark staining in the tooth’s deep pits and fissures that may be a result of tobacco use or tartar build up.
- Trauma—Usually involves maxillary incisors common in sports, accidents, violence, and epilepsy.
- Tooth erosion—Results from consumption of carbonated beverages and fruit drinks, repeated vomiting associated with eating disorders, gastroesophageal reflux, and alcoholism.
- Tooth attrition—Wearing down of teeth because of tooth grinding (bruxism) or an abrasive diet.
- Tooth abrasion—Caused by brushing with a hard toothbrush and using abrasive toothpaste.
- Bulimia can cause destruction of the teeth because of the gastric acids (**Figure 45-3**).

MANAGEMENT

- Demineralized lesions (“white spots”) and caries—Topical fluorides such as varnishes (5% NaF; 23,000 parts per million [ppm] F⁻) that are applied by dental health providers or the primary care physician twice a year have been shown to decrease dental caries by 21%.⁷
- Fluoride mouth rinses (0.2% NaF, 900 ppm F⁻) are effective in controlling caries when used daily.⁷
- Refer to a dental health professional for sealant treatment of pits and fissures.⁸

FIGURE 45-3 Destruction of the teeth in woman with bulimia. The gastric acids have dissolved the enamel. (Courtesy of Gerald Ferretti, DMD.)

- Refer patients with “white spots” and dental caries to a dental professional for treatment and/or restoration.⁵
- Patients with xerostomia may be treated with saliva substitutes such as Oralbalance in the Biotene product range.⁵

PREVENTION AND SCREENING

Most oral disease, including cavities, is preventable. Proper oral hygiene (daily brushing and flossing), daily exposure to fluoride (systemic or topical), along with a healthy diet that is not high in sugar, can prevent the formation and/or progression of dental caries. Visual screening can detect caries at the early stages.

PROGNOSIS

The prognosis for lesions that are detected during their early stages or prior to approximating the tooth's nerve is very good. Removal of the carious portion of the tooth and placement of a filling will restore the tooth to function and prevent further progression of the cavity.

FOLLOW-UP

Remind adult patients who have incipient “white-spot” caries or active caries to go to a dentist for treatment. Patients with large caries should be referred for immediate treatment.

PATIENT EDUCATION

- Advise patients to maintain good oral hygiene by brushing their teeth twice daily with a small-headed, soft to medium hardness brush using a toothpaste that contains fluoride. Electric toothbrushes may be useful for those with poor manual dexterity. Counsel patients to floss once daily to remove plaque and food particles from between the teeth.
- Suggest that patients use antiplaque mouthwashes containing chlorhexidine to inhibit *S. mutans*, but caution coffee, tea, and red wine drinkers that such mouthwashes may increase dental staining.⁵
- Patients with xerostomia (dry mouth) should be advised to practice good oral hygiene, increase water intake, and avoid sugary foods. Chewing sugar-free gum will induce salivation.⁵
- Patients with xerostomia should also be advised to avoid alcohol-containing mouth rinses, as alcohol also dries the mouth.
- Advise patients that plaque formation may be reduced by chewing sugar-free gum and eating raw fruits and vegetables, which reduces bacteria through mechanical cleansing of the tooth surfaces.
- Patients who use asthma inhalers should be advised to rinse their mouth out with water after inhaler use to decrease the amount of residue that is left in the oral cavity. Many inhalers contain lactose, a fermentable sugar.
- Eating calcium-containing foods, such as milk and cheese, helps buffer the acidic environment and helps with remineralization.

- Advise patients to visit a dental professional at least once a year for a cleaning and examination.

SECTION 1 CENTRAL

46 CORONARY ARTERY
DISEASE

Heidi Chumley, MD

PATIENT STORY

A 45-year-old man began having chest pressure with exertion that was relieved with rest. He did not have diabetes, high blood pressure, or high cholesterol, and had never had a myocardial infarction. His examination and resting ECG were normal. On the basis of the testing modalities available, he was scheduled for exercise stress testing. After a positive test, he underwent coronary angiography that demonstrated a significant stenosis in the left coronary artery (**Figure 46-1**). He underwent a stenting procedure and was placed on aspirin and cholesterol-lowering medication.

INTRODUCTION

In the United States, a person dies of coronary heart disease every 39 seconds. Coronary heart disease is a manifestation of atherosclerotic disease and has many modifiable risk factors. Patients with and without coronary heart disease should be advised to stop smoking, maintain normal blood pressure and cholesterol levels, exercise, achieve or maintain a normal weight, and control diabetes mellitus if present.

EPIDEMIOLOGY

- Coronary heart disease (CHD) is the leading cause of death in the United States, responsible for approximately 400,000 deaths in 2008.¹
- Each year, 1.5 million myocardial infarctions occur (first and recurrent) with a 33% mortality rate.¹
- In 2005, the prevalence of CHD among U.S. adults older than 18 years of age was higher in men than woman (8.2% vs. 5.0%) and higher in people with a less-than-high-school-diploma education (9.8% vs. 5.0% for college graduates).²

In 2005, prevalence among white and black persons was similar.²

ETIOLOGY AND PATHOPHYSIOLOGY

- CHD is one of several manifestations of atherosclerotic disease, which begins with endothelium dysfunction.³
- Endothelium, when normal, balances vasoconstrictors and vasodilators, impedes platelet aggregation, and controls fibrin production.

FIGURE 46-1 Coronary arteriogram demonstrating severe stenosis (white arrow) in the left coronary artery. Note that the circumflex artery (CX) is patent.

- Dysfunctional endothelium encourages macrophage adhesion, plaque growth, and vasoconstriction by recruiting inflammatory cells into the vessel walls, the initiating step of atherosclerosis.
- The vessel wall lesions develop a cap of smooth muscle cells and collagen to become fibroadenomas.
- The vessels with these lesions undergo enlargement, allowing progression of the plaque without compromising the lumen.
- Plaque disruption and thrombus formation, instead of progressive narrowing of the coronary artery lumen, is responsible for two-thirds of acute coronary events.²
- Plaques most likely to rupture (high-risk plaques) have a large core of lipids, many macrophages, decreased vascular smooth muscle cells, and a thin fibrous cap.
- After plaque rupture, the exposed lipid core triggers a superimposed thrombus that occludes the vessel.
- Increased thrombosis is triggered by known cardiac risk factors including elevated low-density lipoprotein (LDL) cholesterol, cigarette smoking, and hyperglycemia.
- The other one-third of acute coronary events occurs at the site of very stenotic lesions (**Figure 46-2**).³

FIGURE 46-2. Coronary angiogram of a left coronary artery (LCA) with a tight stenosis in the proximal left anterior descending (LAD) artery (black arrow). The circumflex artery (CX) has 2 moderately severe stenoses (white arrows).

RISK FACTORS

- Family history of premature paternal or sibling myocardial infarction increases risk of heart disease by 50%.¹
- Tobacco use and secondhand smoke exposure increase the risk of CHD and smoking cessation reduces risk.¹
- High total cholesterol, high LDL, and/or low high-density lipoprotein (HDL) are independent risk factors.
- Physical inactivity has a relative risk of CHD of 1.5 to 2.4.¹
- Overweight and obesity increases risk of heart disease by 20% (men and women) and 46% (men)/64% (women), respectively.¹
- Diabetes mellitus increases risk of heart disease (hazard ratio 2.5).¹

DIAGNOSIS

CLINICAL FEATURES

- Typical angina is chest pain or pressure, brought on by exertion or stress, and relieved with rest or nitroglycerin.
- Atypical angina has two of the three features of typical angina; however, women with coronary artery disease report more neck, throat, or jaw pain.⁴
- Noncardiac chest pain has zero to one of the three features of typical angina.

LABORATORY TESTING

- Risk factor assessment—Lipid profile and fasting blood glucose.
- Acute coronary syndrome—Cardiac-specific troponin is now preferred; when troponin cutoff is 0.1 g/L, sensitivity is 93%,

specificity is 91%, positive likelihood ratio (LR+) is 10.33, and negative likelihood ratio (LR-) is 0.08.

COMMON NONINVASIVE TESTING⁵

- Exercise treadmill testing—Sensitivity 52% and specificity 71%, LR+ 1.79, LR- 0.68.
- Stress echocardiogram—Sensitivity 85% and specificity 77%, LR+ 3.70, LR- 0.19.
- Stress thallium—Sensitivity 87% and specificity 64%, LR+ 2.42, LR- 0.20.

Newer methods being tested include CT for diagnosis:⁶

- A 4- or 16-slice study—Sensitivity 95% and specificity 84%, LR+ 5.94, LR- 0.06, with 78% and 91% of segments evaluable.
- A 64-slice study—Sensitivity 100% and specificity 100% with 100% of segments evaluable.

DIFFERENTIAL DIAGNOSIS

Chest pain can be caused by several conditions including:

- Cardiac—Pericarditis—slower onset of pain, pain aggravated by movement or inspiration, characteristic ECG changes.
- Respiratory—Pneumothorax—acute onset with shortness of breath and characteristic radiographic findings; pneumonia—often accompanied by fever, cough, shortness of breath/hypoxia, and/or radiographic findings; pulmonary embolism—acute onset of shortness of breath, positive ventilation-perfusion scan, or spiral CT.
- GI—Gastroesophageal reflux—related to eating, responds to H₂ blockers or proton pump inhibitor (PPI).
- Musculoskeletal—Costochondritis—chest muscles tender to palpation.

MANAGEMENT

NONPHARMACOLOGIC

- Advise patients with coronary artery disease to stop smoking.⁷ **SOR A**
- Recommend 30 minutes of physical activity 5 to 7 days per week.^{1,7} **SOR B**
- Advise patients in weight management with a goal body mass index (BMI) of 18.5 to 24.9.⁷ **SOR B**

MEDICATIONS

Managing risk factors:

- Lower LDL cholesterol using lifestyle modification and hydroxymethylglutaryl coenzyme A (HMG-CoA) reductase inhibitors to decrease all-cause mortality (relative risk [RR] 0.90), cardiovascular mortality (RR 0.80), fatal and nonfatal myocardial infarction (MI) (RR 0.82 and 0.74).⁸ **SOR A**

- Lower blood pressure to 140/90 or 130/80 mm Hg (with diabetes or chronic renal disease); treat patients who are post-MI with a β -blocker, thiazide diuretic, or aldosterone antagonist.⁹ **SOR A**
- Prescribe aspirin in patients with prior ST elevation or non-ST elevation acute coronary event or chronic stable angina. Prescribe clopidogrel alone in chronic stable angina or with aspirin in non-ST elevation acute coronary syndrome.¹⁰ **SOR A**
- Prescribe a β -antagonist—Several trials demonstrate mortality decreases of 25% to 40% with various β -blockers used in the acute MI or post-MI period.¹¹

Treat symptoms:

- Nitroglycerin sublingual or spray for immediate relief of angina.¹² **SOR B**
- Long-acting nitrates or calcium antagonists if β -blockers are contraindicated, do not control symptoms, or have unacceptable side effects.¹² **SOR B**

REFERRAL OR HOSPITALIZATION

- Refer patients with positive noninvasive testing to be evaluated for cardiac catheterization.
- Consult with cardiologists and cardiothoracic surgeons to determine optimal management.
- Traditionally, patients with greater than 50% stenosis of left main, proximal stenosis of three major arteries, or significant stenosis of the proximal left anterior descending and one other major artery have been treated with coronary bypass surgery.¹³ **SOR A**
- Advancements with drug-eluting stents may increase the numbers and types of patients who benefit from stenting.¹³

PREVENTION

Prevention of CHD is accomplished by risk factor control. In a study of older men that examined the risk factors of smoking, high LDL, high blood pressure, and no aspirin use, the number needed to treat (NNT) to prevent one cardiovascular outcome were: 22, 8, 6, and 5 for 1, 2, 3, and 4 risk factors controlled, respectively.¹⁴

FOLLOW-UP

Follow-up frequency is based on the extent of illness and symptoms and may include primary care and subspecialty care. Patients should have ongoing evaluation of risk factors and symptoms every 4 to 12 months. Expert guidelines recommend annual exercise stress testing for patients with chronic stable angina.¹² **SOR C**

PATIENT EDUCATION

Advise patients in the importance of lifestyle modification and medications in the long-term management of CHD.

47 HYPERTENSION

Heidi Chumley, MD

PATIENT STORY

A 40-year-old man presents after his blood pressure was measured as 180/100 mm Hg at a health screening. He has no complaints. His blood pressure today was 178/98 mm Hg. Based on these two readings, he is diagnosed with stage 2 hypertension. His family history is very positive for essential hypertension. His examination is normal other than an enlarged and laterally displaced point of maximal impulse. His body mass index is normal. The provider sends him for a urinalysis, complete blood count (CBC), fasting lipid profile, and a chemistry panel that includes blood glucose, potassium, serum creatinine, and calcium. An ECG shows left ventricular hypertrophy (**Figure 47-1**). He is counseled regarding lifestyle change, started on 2 medications, and asked to follow-up within a couple of weeks.

INTRODUCTION

Hypertension (HTN) is a major risk factor for both myocardial infarction and stroke. Primary HTN constitutes 90% of HTN cases. Initial

FIGURE 47-1 EKG showing left ventricular hypertrophy in this 58-year-old man with current blood pressure of 178/98. Note how $S V_1 + R V_5 > 35$ mm. Also his EKG shows left axis deviation and non-specific ST changes in the high lateral leads (I and aVL). (Courtesy of Gary Ferenchick, MD.)

treatment includes lifestyle modifications and medications. Most patients require at least 2 medications to achieve control. Patients who are not controlled on 3 medications should undergo a work-up for secondary causes.

EPIDEMIOLOGY

- Of U.S. adults older than age 18 years, 29% have HTN.¹
- Blood pressure is controlled in approximately 50% of adults with HTN.¹
- Blood pressure control is lowest among those without health insurance (29%), Mexican Americans (37%), and adults ages 18 to 39 years (31%).^{1,2}
- In the United States, HTN contributes to 1 of every 7 deaths and to half of the cardiovascular disease-related deaths.²
- Cost of HTN to the U.S. healthcare system is estimated to be \$93.5 billion per year.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Primary HTN (>90% of patients)—The specific cause is unknown, but environmental factors (i.e., salt intake, excess alcohol intake, obesity) and genetics both play a role.
- Secondary HTN (5% to 10% of patients)—Causes include medications, kidney disease, renal artery stenosis (**Figure 47-2**), thyroid disease, hyperaldosteronism, and sleep apnea. Rare causes include coarctation of the aorta, Cushing syndrome and pheochromocytoma.

RISK FACTORS

- Family history/genetic predisposition.
- Obesity.
- High sodium chloride intake.
- Medications, including oral contraceptives, NSAIDs, decongestants, and some antidepressants.
- Substances, including caffeine, licorice, amphetamines, cocaine, tobacco.

DIAGNOSIS

Average of 2 or more seated blood pressure readings on each of 2 or more office visits, based on systolic (SBP) and diastolic (DBP) blood pressures.

- Prehypertension—SBP 120 to 139 mm Hg or DBP 80 to 89 mm Hg.
- Stage 1 HTN—SBP 140 to 159 mm Hg or DBP 90 to 99 mm Hg.
- Stage 2 HTN—SBP equal to or greater than 160 mm Hg or DBP equal to or greater than 100 mm Hg.

FIGURE 47-2 Angiogram revealing bilateral renal artery stenosis (arrows), one of the more common causes of secondary hypertension, most often a result of atherosclerotic disease in older patients. (From Figure 111-15A in *Hurst's the Heart* 13th ed.)

CLINICAL FEATURES

- No symptoms may be present.
- When blood pressure is high, patients may have headaches, vision changes, confusion, chest pain/myocardial infarction, pulmonary edema, stroke or hematuria.
- Hypertensive retinopathy may be present (**Figure 47-3** and Chapter 21, Hypertensive retinopathy).
- An S4 can be an early physical examination finding.
- Left ventricular hypertrophy may be manifest as an enlarged laterally displaced point of maximal impulse, abnormal ECG (**Figure 47-1**), or abnormal chest radiograph.
- Abdominal bruits may be present with renal artery stenosis.

LABORATORY TESTING

- Before initiating therapy for presumed primary HTN perform the following tests: urinalysis, CBC, fasting lipid profile, and chemistry panel, including fasting blood glucose, potassium, creatinine, and calcium.
- Consider testing for thyroid disorders with a thyroid-stimulating hormone (TSH) if other signs or symptoms are present.
- For patients with abnormal screening tests, signs indicating a secondary cause, or inadequate control on 3 medications:
 - Serum aldosterone and plasma renin activity are useful in patients with hypokalemia.
 - 24-hour urine protein and creatinine for suspected renal disease.
 - A 24-hour urine free cortisol or a dexamethasone suppression test for suspected Cushing syndrome.
 - Plasma and urine catecholamines or metanephrines for suspected pheochromocytoma.
 - Parathyroid hormone level for suspected hyperparathyroidism.

IMAGING AND ANCILLARY TESTS

- ECG on all patients with HTN.
- Chest radiograph is usually not ordered for primary HTN; however, if obtained, cardiomegaly may be present. If coarctation of the aorta is expected, rib notching may be present.
- Echocardiogram may also demonstrate left ventricular hypertrophy.
- Renal artery stenosis can be seen on magnetic resonance angiography or by angiography (**Figure 47-2**).
- Renal ultrasound may demonstrate small or absent kidney.

DIFFERENTIAL DIAGNOSIS

- Falsely elevated blood pressure readings can be a result of improper cuff size (too small with a large arm diameter) or method (patient not seated, arm in incorrect position, etc).
- Acute elevations in blood pressure may be caused by substances (e.g., tobacco).
- White coat HTN is defined as blood pressure that is consistently over 140/90 mm Hg in the presence of a healthcare provider with an ambulatory monitoring average of less than 135/85 mm Hg.

FIGURE 47-3 Hypertensive and diabetic retinopathy with dot-blot hemorrhages, a flame hemorrhage, and hard exudates. The arterioles are attenuated from the hypertension. (Courtesy of Carrie Cooke.)

MANAGEMENT

NONPHARMACOLOGIC

- Weight reduction if overweight or obese
- DASH (dietary approaches to stop hypertension) diet, rich in fruits and vegetables, aimed at reducing sodium intake and eating a variety of foods rich in nutrients that help lower blood pressure, such as potassium, calcium, and magnesium.
- Low-fat diet.
- Low dietary sodium chloride.
- Regular aerobic exercise.
- Moderate alcohol intake: no more than 2 drinks per day for men and 1 drink per day for women.
- Smoking cessation for cardiovascular risk reduction (see Chapter 236, Tobacco Addiction).

MEDICATIONS

- Start a thiazide-type diuretic in most patients. An angiotensin converting enzyme inhibitor (ACEI) may be the initial choice in white males.
- Consider starting 2 medications when blood pressure is 20/10 mm Hg higher than goal. Goal is 140/90 mm Hg or 130/80 mm Hg in patients with diabetes or chronic kidney disease.
- Add an ACEI, angiotensin receptor blocker (ARB), β -blocker (BB), or calcium channel blocker (CCB) if control is not achieved with initial agent.
- Specific medications have compelling indications in these situations:
 - Heart failure—Diuretic, BB, ACEI, ARB, aldosterone antagonist (AA).
 - Postmyocardial infarction—BB, ACEI, AA.
 - Diabetes—Diuretic, BB, ACEI, ARB, CCB.
 - Chronic kidney disease—ACEI, ARB.
 - Recurrent stroke prevention—Diuretic, ACEI.

REFERRAL OR HOSPITALIZATION

- Refer patients in whom adequate blood pressure control is not obtained.
- Women with HTN who are planning a pregnancy or who become pregnant should be referred to a provider with experience managing chronic HTN in pregnancy.

PREVENTION

Healthy lifestyle for all persons, including weight reduction (if overweight or obese), use of DASH, initiation and maintenance of adequate physical activity, and moderate alcohol intake.

PROGNOSIS

- Risk of cardiovascular disease increases as blood pressure increases.

- Between 115/75 and 185/115 mm Hg, every 20 mm Hg systolic BP or 10 mm Hg diastolic BP doubles the risk of cardiovascular disease for adults ages 40 to 70 years.³

FOLLOW-UP

- Schedule visits monthly until blood pressure goal is obtained.
- Consider more frequent visits for patients with stage 2 HTN or significant comorbid conditions.
- See patients with controlled HTN every 3 to 6 months.

PATIENT EDUCATION

- HTN is a chronic disease requiring lifelong lifestyle modifications and 1 or more daily medications for most patients.
- Adequate control of HTN reduces the risk for heart attack and stroke.

48 HEART FAILURE

Heidi Chumley, MD

PATIENT STORY

A 60-year-old man presents to the emergency department with shortness of breath increasing in severity over the past several days, along with paroxysmal nocturnal dyspnea and orthopnea. He does not have a history of heart failure or previous myocardial infarction. On examination it was found that he had a third heart sound and an elevated jugular venous pressure. His chest radiograph showed cardiomegaly (**Figure 48-1**) and his B-type natriuretic peptide (BNP) was elevated at 600 pg/mL. He was diagnosed with heart failure, evaluated for underlying causes including coronary artery disease, and treated initially with an angiotensin-converting enzyme inhibitor (ACEI) and a diuretic. Later, he will be started on a β -blocker and an aldosterone inhibitor.

INTRODUCTION

Heart failure (HF) is common and increases with age. Multiple etiologies can cause the decrease in heart pumping capacity that leads to HF. ACEIs and β -blockers with or without aldosterone agonists and angiotensin II blockers are the main pharmacologic therapies.

SYNONYMS

Congestive heart failure (CHF).

EPIDEMIOLOGY

- The prevalence of HF in the community increases with age: 0.7% (45 to 54 years); 1.3% (55 to 64 years); 1.5% (65 to 74 years); and 8.4% (75 years or older).¹
- More than 40% of patients in the community with HF have an ejection fraction greater than 50%.¹
- At age 40 years, the lifetime risk for HF is 21.0% (95% confidence interval [CI] 18.7% to 23.2%) for men and 20.3% (95% CI 18.2% to 22.5%) for women.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Heart pumping capacity declines from any cause (i.e., myocardial infarction or ischemia, hypertension, valvular dysfunction, cardiomyopathy, or infections such as endocarditis or myocarditis).
- Cardiac dysfunction activates the adrenergic and renin-angiotensin-aldosterone systems.
- These systems provide short-term compensation, but chronic activation leads to myocardial remodeling and eventually worsening cardiac function.

FIGURE 48-1 Cardiomegaly demonstrated in a posteroanterior (PA) view. The widest part of the heart is greater than 50% of the diameter of the chest. (Courtesy of Heidi Chumley, MD.)

- Norepinephrine, angiotensin II, aldosterone, and tissue necrosis factor each contribute to disease progression.
- Angiotensin II directly causes cell death through necrosis and apoptosis, as well as cardiac hypertrophy.

DIAGNOSIS

Many history, examination, radiographic, ECG, and laboratory features are helpful in making the diagnosis of HF for patients presenting with dyspnea in the emergency department:³

CLINICAL FEATURES

- History and physical
 - History of HF (LR + [likelihood ratio] = 5.8), myocardial infarction (LR+ = 3.1).³
 - Symptoms of paroxysmal nocturnal dyspnea (LR+ = 2.6), orthopnea (LR+ = 2.2), edema (LR+ = 2.1).³
 - Examination finding of third heart sound (LR+ = 11), hepatojugular reflex (LR+ = 6.4), jugular venous distention (LR+ = 5.1).³

LABORATORY AND ANCILLARY TESTING

- Laboratory value of BNP ≥ 250 (LR+ = 4.6); BNP < 100 decreases likelihood of HF.³
- ECG finding of atrial fibrillation (LR+ = 3.8), T-wave changes (LR+ = 3.0), any abnormality (LR+ = 2.2). A normal ECG lowers likelihood (LR- = 0.640).³

IMAGING

- Radiographic finding of pulmonary venous congestion (**Figure 48-2**) (LR+ = 12.0), interstitial edema (LR+ = 12.0), alveolar edema (LR+ = 6.0), cardiomegaly (**Figures 48-1 to 48-3**) (LR+ = 3.3).³

DIFFERENTIAL DIAGNOSIS

Gradually increasing shortness of breath can also be caused by:

- Chronic obstructive pulmonary disease may have dyspnea with exertion but does not have orthopnea; chest radiograph shows a normal size heart, hyperinflated lungs, and flattened diaphragm; pulmonary function tests may be abnormal.
- Deconditioning has a normal chest radiograph.
- Metabolic acidosis from any cause can be differentiated with an arterial blood gas.
- Anxiety has episodic shortness of breath, not associated with exertion and a normal chest radiograph.
- Neuromuscular weakness may have abnormal pulmonary function tests and a normal chest radiograph.
- Pneumonia may have fever and an infiltrate on chest radiograph.

MANAGEMENT

NONPHARMACOLOGIC

- Telemonitoring of patients with known HF reduced all-cause mortality (relative risk [RR] 0.66). Telemonitoring and structure

FIGURE 48-2 Cardiomegaly with pulmonary venous congestion and bilateral pleural effusions. (Courtesy of Heidi Chumley, MD.)

telephone support reduced HF related hospitalization (RR 0.79 and 0.77, respectively).⁴

- Exercise rehabilitation increases quality of life and decreases hospital admissions in patients with left ventricular systolic dysfunction.⁵
- Salt restriction *increased* all-cause mortality in patients with HF (RR 0.84).⁶

MEDICATIONS

Individually, ACEIs, β -blockers, and aldosterone antagonists (AAs) lower mortality and should be considered for all patients without contraindications.

- Prescribe an ACEI. **SOR A** ACEIs lower mortality rates by 23% overall. Use in patients with asymptomatic left ventricular dysfunction and all other stages of HF.⁷
- Prescribe a β -blocker. **SOR A** β -Blockers reduce mortality by 32%.⁸ Begin at a small dose and double the dose every 2 to 4 weeks until the target dose is reached or the patient cannot tolerate the increased dose. One study demonstrating a decrease in mortality had a large percentage of patients in the control and intervention groups already on an ACEI, indicating that the two together may decrease mortality more than an ACEI alone.⁷ **SOR B**
- Prescribe an AA when the creatinine is less than 2.0; monitor renal function and potassium.⁷ **SOR A** AAs lowered mortality in patients already on ACEI.⁸ **SOR B**
- Consider an angiotensin II receptor blocker (ARB) for patients who cannot tolerate an ACEI.⁴ Patients with moderate, severe, or advanced HF may benefit from an ACEI plus an ARB or AA **SOR B**, but the safety of all three is unknown.⁷
- After a myocardial infarction, an ARB has shown equivalent reductions in mortality to an ACEI, but the combination does not improve outcomes.

Nonpotassium sparing diuretics, calcium channel blockers, and digoxin may improve symptoms but do not lower mortality.

- Nonpotassium sparing diuretics (e.g., furosemide) have been associated with worse outcomes, including higher mortality when used alone. Use for volume overload with ACEI, β -blocker, AA \pm ARB as above.⁸
- Calcium channel blockers (verapamil and nifedipine) are avoided in systolic HF. Calcium channel blockers improve symptoms in diastolic HF, but do not lower mortality.⁹ **SOR A**
- Digoxin reduces hospitalizations and improves clinical symptoms, but does not lower mortality.⁸ Consider adding digoxin when patients have symptoms despite adequate therapy with ACEI, β -blockers, AA \pm ARB.

REFERRAL OR HOSPITALIZE

- Refer for evaluation for cardiac resynchronization therapy in patients with left ventricular ejection fraction (LVEF) less than 35% and QRS greater than 150 milliseconds.⁵ A recent metaanalysis demonstrated that cardiac resynchronization therapy decreased all-cause mortality and hospitalizations for HF in patients with

FIGURE 48-3 Cardiomegaly with increased pulmonary vasculature and Kerley B lines (2- to 3-cm horizontal lines in the lower lung fields). (Courtesy of Heidi Chumley, MD.)

New York Heart Association (NYHA) class II. Number needed to treat (NNT) = 12 to prevent 1 hospitalization.¹⁰

- Refer for evaluation for implantable cardiac defibrillator (ICD) placement in patients with NYHA class II-IV and LVEF less than 35%. **SOR C** ICDs have been shown to reduce mortality up to 30% and may offer greater risk reduction than antiarrhythmic medical therapy for some patients.¹¹

PROGNOSIS

Absolute mortality is high in patients with HF.

- Patients with preserved ejection fraction (>50%) have a mortality rate of 121 per 1000 patient years.¹²
- Patients with reduced ejection fraction (<40%) have a mortality rate of 141 per 1000 patient years.¹²

FOLLOW-UP

Close follow-up in many forms, including telemedicine and structured telephone visits, can reduce hospitalizations and mortality.⁴

PATIENT EDUCATION

Fluid and sodium restriction are often advised, but a recent Cochrane review demonstrated an increased mortality with sodium restriction.

49 PERICARDIAL EFFUSION

Heidi Chumley, MD

PATIENT STORY

A 30-year-old woman presented to her family physician with increasing shortness of breath over the past 2 weeks. Prior to this, she had a flu-like illness and felt like she never recovered. She denied chest pain and edema, did not take any medications, and had not had any recent trauma or surgery. She had a normal examination. Her chest radiograph showed a classic globular heart as demonstrated in **Figure 49-1**. She had nonspecific ST changes on her ECG. An echocardiogram confirmed pericardial effusion (**Figure 49-2**). The underlying etiology was not elucidated and she recovered spontaneously over the next several months.

INTRODUCTION

Pericardial effusions are commonly found in the general population and the incidence increases with age. They can be caused by cardiac disease or surgery, connective tissue disorders, neoplasms, infections, renal disease, hypothyroidism, or medications; however, a cause is identified only 50% of the time. The definitive diagnosis is made by echocardiography.

EPIDEMIOLOGY

- Six-and-a-half percent of adults (<1% ages 20 to 30 years; 15% older than 80 years of age) had echocardiogram findings consistent with pericardial effusion in a population-based study of 5652 adults and adult family members of participants in the Framingham Heart Study.¹
- Seventy-seven percent of patients after cardiac surgery for valves or bypass have pericardial effusions, which rarely (<1%) require therapy.²
- Forty percent of healthy pregnant women have small, asymptomatic pericardial effusions in the third trimester.³

ETIOLOGY AND PATHOPHYSIOLOGY

Pericardial effusion, acute or chronic, occurs when there is increased production or decreased drainage of pericardial fluid allowing accumulation in the pericardial space.

The underlying etiology is apparent clinically approximately 25% of the time and can be determined with testing in another 25% of cases, leaving 50% of cases idiopathic.⁴ Most idiopathic cases have small effusions. Moderate to large pericardial effusions have an identifiable cause in 90%.⁵

FIGURE 49-1 Globular cardiac silhouette or classic “water-bottle heart” seen with a pericardial effusion can be difficult to distinguish from cardiomegaly on plain radiographs. (Courtesy of Heidi Chumley, MD.)

FIGURE 49-2 Echocardiogram showing right ventricular (RV) compression from a pericardial effusion (PE). LV, Left ventricle; RA, right atrium. (Courtesy of Heidi Chumley, MD.)

RISK FACTORS

Underlying causes include:

- Congestive heart failure from other cardiac diseases, such as rheumatic heart disease, cor pulmonale, or cardiomyopathy.⁶
- After cardiac surgery or after a myocardial infarction.²
- Connective tissue disorders (scleroderma, lupus erythematosus, rheumatoid arthritis).⁶
- Neoplasms: benign (atrial myxoma); primary malignant (mesothelioma); secondary malignant (i.e., lung or breast cancer).⁶
- Chronic renal disease (uremia or hemodialysis) or other causes of hypoalbuminemia.
- Infections: acute (enterovirus, adenovirus, influenza virus, *Streptococcus pneumoniae*, *Coxiella burnetii*—responsible for Q fever) or chronic (tuberculosis, fungus, parasites).⁴
- Medications (procainamide, hydralazine) or after radiation.⁶
- Severe hypothyroidism with myxedema.⁶

DIAGNOSIS

Clinical features, chest radiograph, and electrocardiogram suggest pericardial effusion, which is confirmed by echocardiogram. The underlying etiology is identifiable in approximately 50% of cases.

CLINICAL FEATURES

Signs and symptoms occur when the volume of fluid is large enough to affect hemodynamics. This occurs at 150 to 200 mL in acute pericardial effusion. Chronic pericardial effusion allows stretching overtime and may require up to 2 L to cause significant symptoms:⁶

- Hypotension, increased jugular venous pressure, and soft heart sounds form the classic triad of acute cardiac tamponade, but all three are present only in approximately 30% of cases.⁶
- Common symptoms include anorexia (90%), dyspnea (78%), cough (47%), and chest pain (27%).⁶
- Common physical examination findings include pulsus paradoxus (77% with acute tamponade, 30% with chronic effusions), sinus tachycardia (50%), jugular venous distention (45%), hepatomegaly and peripheral edema (35%).⁶

LABORATORY AND ANCILLARY TESTING

- Electrocardiogram is abnormal in 90%. Findings include low QRS voltage and nonspecific ST-T changes (59% to 63%) and electrical alternans (0% to 10%).⁶

When the diagnosis remains unclear, pericardial fluid can be sent for cell count and differential, protein, lactate dehydrogenase, glucose, Gram stain, bacterial cultures, fungal cultures, mycobacterial acid-fast stain and culture, and tumor cytology. Measure rheumatoid factor, antinuclear antibody, and complement levels when collagen vascular disease is suspected.⁶ Check HIV status in at-risk patients.

When there is no obvious cause, ordering this set of specific tests determined the underlying etiology more often than seen in historic controls (27.3% vs. 3.9%; $p < 0.001$).⁷

- Aerobic and anaerobic blood cultures.
- Throat swab cultures for influenza, adenovirus, and enterovirus.
- Serologic tests for *Cytomegalovirus*, influenza, *C. burnetii*, *Mycoplasma pneumoniae*, and *Toxoplasma*.
- Blood tests for antinuclear antibody (ANA) and thyroid-stimulating hormone (TSH).

IMAGING

- Chest radiograph shows a globular enlarged cardiac silhouette (**Figure 49-1**) (sensitivity 78%, specificity 34% with moderate or severe effusions) and pericardial fat stripe (**Figure 49-3**) (sensitivity 22%, specificity 92%).⁶
- Echocardiography is the preferred imaging test. Echo can be used to quantify volume of pericardial effusion (correlation to amount of fluid withdrawn 0.7).⁸ Echo-free, as opposed to echogenic fluid, is associated with a lower risk of constrictive pericarditis or recurrent pleural effusion.⁹
- CT scanning, typically done for another purpose, can demonstrate the presence of a pericardial effusion, but does not quantify volume as well as echocardiography (correlation to amount of fluid withdrawn 0.4).⁸

DIFFERENTIAL DIAGNOSIS

- Congestive heart failure has many similar signs and symptoms (dyspnea, jugular venous distention, hepatomegaly, and edema) but may have pulmonary rales, which are unusual in pericardial

FIGURE 49-3 Moderate pericardial effusion is seen as a wide pericardium (arrow). (Courtesy of Heidi Chumley, MD.)

FIGURE 49-4 The lateral view demonstrates the normal thin pericardium (arrow), which should be less than 2 mm. (Courtesy of Heidi Chumley, MD.)

effusions. A lateral radiograph in a patient with congestive heart failure (without pleural effusion) should have a normal thin pericardium (**Figure 49-4**).

- Pleural effusions may also present with dyspnea, but have different physical examination and radiographic findings.
- Acute pericarditis (without pericardial effusion) can present with chest pain and nonspecific ECG changes also seen with pericardial effusion. In contrast, acute pericarditis often has elevated inflammatory markers and a normal chest radiograph.

MANAGEMENT

- Treat any identified underlying cause.
- When the diagnosis is unclear and the patient is hemodynamically stable, NSAIDs may be beneficial, especially if inflammatory markers are elevated.
- Pericardiocentesis is required when there is hemodynamic compromise. A pericardiocentesis is also useful when the pericardial effusion is large or suspected to be secondary to a bacterial infection or neoplastic process.
- Pericardiocentesis is performed by a specialist under local anesthesia as follows: Elevate the patient to a 45-degree angle. Insert a needle in the angle between the left costal arch and the xiphoid process, directed 15-degrees posterior, and angled toward the head or either shoulder. Complications are reduced when this procedure is guided by echocardiography. Fluid often reaccumulates. An

indwelling catheter can be placed for up to 72 hours without increasing the risk of infection, until a more permanent procedure can be performed to decrease the likelihood of reaccumulation.

- Sclerosing therapy reduces the recurrence of symptoms from reaccumulation or the need for a repeat procedure for 30 days in more than 70% of patients. A caustic substance such as bleomycin or tetracycline is instilled into the pericardial space and held there for up to 4 hours.
- Other options to reduce recurrence include balloon pericardiectomy performed in a cardiac catheterization laboratory, radiation therapy, and surgery (i.e., pericardial window).

PROGNOSIS

Prognosis depends on the underlying cause.

In a study of older adults undergoing echocardiography for reasons other than a pericardial effusion, patients with an incidental small pericardial effusion had a higher 1-year mortality (26%) than did patients without an effusion (11%).¹⁰

FOLLOW-UP

Follow-up is based on the underlying cause. Pericardial effusions often disappear when the underlying illness resolves, and reappear when the underlying illness does not resolve (metastatic cancer).

PATIENT EDUCATION

- The underlying cause of a pericardial effusion is identified only 50% of the time; however, specific tests should be done to find treatable causes.
- In patients without an obvious underlying illness, infections (like the flu, Q fever, or tuberculosis) and cancer are the two most commonly identified causes of pericardial effusions.

50 BACTERIAL ENDOCARDITIS

Heidi Chumley, MD

PATIENT STORY

A 25-year-old man presented to the office because he had been feeling tired and feverish for several weeks. He admitted to injecting heroin regularly in the last 2 months. On examination, he was febrile and had a heart murmur of which he was previously unaware. His fingernails showed splinter hemorrhages (**Figure 50-1**). His fundoscopic examination revealed Roth spots (**Figures 50-2 and 50-3**). An echocardiogram demonstrated vegetation on the tricuspid valve. He was hospitalized and treated empirically for bacterial endocarditis. After his blood cultures returned *Staphylococcus aureus*, his regimen was adjusted based on sensitivities and continued for 6 weeks.

INTRODUCTION

Bacterial endocarditis is a serious infection seen most commonly in patients with prosthetic valves; injection drug users; patients with HIV, especially those who use intravenous (IV) drugs; and patients who are immunosuppressed. Diagnosis is made based on Duke Criteria. Treatment is IV antibiotics. Mortality, despite treatment, is 26% to 37%.

EPIDEMIOLOGY

- 5.0 to 7.9 cases per 100,000 patient-years.¹
 - Historically more common in men; however, the incidence in women is increasing. Men and women 8.6 to 12.7 and 1.4 to 6.7 cases per 100,000 person-years, respectively.¹
 - Average age has increased from 46.5 years (1980-1984) to 70 years (2001-2006).¹
 - Incidence in IV drug users is 3 per 1000 person-years or 1% to 5% per year.²
 - Incidence in HIV-positive IV drug users is 13.8 per 1000 person-years.²
- Seen in immunosuppressed patients with central venous catheters or hemodialysis patients.
 - Fifty percent healthcare-associated, 43% community-acquired, and 7.5% nosocomial.¹
 - Mortality ranges from 16% to 37%.³
- Prosthetic valve endocarditis makes up 10% to 15% of endocarditis cases.⁴
 - Incidence of 0.1% to 2.3% person-year.⁴
 - Can occur early (2 months after surgery) or late.

ETIOLOGY AND PATHOPHYSIOLOGY

- Endothelium is injured by mechanical or inflammatory processes.
- Microbes adhere to compromised endothelium during transient bacteremia.

FIGURE 50-1 Splinter hemorrhages appearing as red linear streaks under the nail plate and within the nail bed. Although endocarditis can cause this, splinter hemorrhages are more commonly seen in psoriasis and trauma. (Courtesy of Richard P. Usatine, MD.)

FIGURE 50-2 Roth spots that are retinal hemorrhages with white centers seen in bacterial endocarditis. These can also be seen in leukemia and diabetes. (Courtesy of Paul D. Comeau.)

- Common organisms include *S. aureus* (IV drug users, nosocomial infections, prosthetic valve patients), *Streptococcus bovis* (elderly patients), enterococci (nosocomial infections), and *Staphylococcus epidermidis* (early infection in prosthetic valve patients).
- Blood contacts subendothelial factors, which promotes coagulation.
- Pathogens bind and activate monocyte, cytokine, and tissue factor production, enlarging the vegetations on the heart valves.
- The vegetations enlarge and damage the heart valves (**Figure 50-4**). This process can lead to death if not treated adequately in time.
- Septic emboli can occur, most commonly in the brain, spleen, or kidney.⁴

RISK FACTORS

- Prosthetic valve.
- Injection drug use.
- HIV infection.
- Immunodeficiency.

DIAGNOSIS

- Duke criteria use a combination of history, physical examination, laboratory, and echocardiogram findings, and have a sensitivity of approximately 80% across several studies.⁵
- Diagnosis is considered definite when patients have two major, one major and three minor, or five minor criteria.⁵
- Diagnosis is considered possible with one major and one minor or three minor criteria.⁵
- Major criteria include:⁵
 - Two separate blood cultures positive with:
 - *Streptococcus viridans*, *S. bovis*, *Haemophilus*, *Actinobacillus*, *Cardiobacterium*, *Eikenella*, *Kingella*.
 - Community-acquired *S. aureus* or *Enterococcus* without a primary focus.
 - Microorganisms consistent with prior positive blood cultures in infective endocarditis.
 - Endocardial involvement as evidenced by:
 - Echocardiogram evidence of vegetation, abscess, or new partial dehiscence of a prosthetic valve.
 - New valvular regurgitation.
 - Minor criteria include:⁵
 - Predisposition (e.g., heart condition such as a congenital or acquired valvular defect, injection drug use, prior history of endocarditis).
 - Temperature $>38^{\circ}\text{C}$ (100.4°F).
 - Clinical signs: arterial emboli, septic pulmonary infarcts, mycotic aneurysms, intracranial hemorrhages, Janeway lesions (**Figures 50-5** and **50-6**).
 - Glomerulonephritis, Osler nodes, Roth spots, or positive rheumatoid factor (**Figures 50-2**, **50-3**, and **50-6**).
 - Positive blood culture not meeting major criteria.
 - Echocardiographic findings consistent with infective endocarditis that do not meet major criteria.

FIGURE 50-3 Close-up of a Roth spot, which is actually a cotton-wool spot surrounded by hemorrhage. The cotton-wool comes from ischemic bursting of axons and the hemorrhage comes from ischemic bursting of an arteriole. (Courtesy of Paul D. Comeau.)

FIGURE 50-4 Pathology specimen of a patient who died of bacterial endocarditis. Bacterial growth can be seen on the three cusps of this heart valve. (Courtesy of Larry Fowler, MD.)

CLINICAL FEATURES

- Fever—Seen in 85% to 99% of patients, typically low-grade, approximately 39°C (102.2°F).
- New or changing heart murmur—Seen in 20% to 80% of patients.
- Septic emboli—Seen in up to 60%, largely dependent on the size (>10 mm) and mobility of the vegetation.
- Intracranial hemorrhages—Seen in 30% to 40% of patients, bleeding from septic emboli or cerebral mycotic aneurysms.
- Mycotic aneurysms—Aneurysms resulting from infectious process in the arterial wall, most commonly in the thoracic aorta, also found in the cerebral arteries.
- Janeway lesions—Very rare, flat, painless, red to bluish-red spots on the palms and soles (**Figures 50-5** and **50-6**).
- Splinter hemorrhages—Red, linear streaks in the nail beds of the fingers or toes (**Figure 50-1**).
- Glomerulonephritis—Immune mediated that can result in hematuria and renal insufficiency, occurs in approximately 15% of patients with endocarditis.
- Osler nodes—Tender, subcutaneous nodules in the pulp of the digits (**Figure 50-6**).
- Roth spots—Retinal hemorrhages from microemboli, seen in approximately 5% of endocarditis (**Figures 50-2** and **50-3**).
- Positive rheumatoid factor—Seen in up to 50% of patients.

TYPICAL DISTRIBUTION

- Native endocarditis: Mitral valve (prior rheumatic fever or mitral valve prolapse), followed by aortic (prior rheumatic fever, calcific aortic stenosis of bicuspid valve).
- Prosthetic valve endocarditis: Site of any prosthetic valve.
- In IV drug users: Tricuspid valve, followed by aortic.

LABORATORY AND ANCILLARY TESTING

In addition to blood cultures, consider a complete blood count for anemia and leukocytosis, erythrocyte sedimentation rate (ESR) (elevated in approximately 90%), and urinalysis for proteinuria or microscopic hematuria (seen in approximately 50%).

- Positive blood culture—First two sets of cultures are positive in 90%.⁴

IMAGING

- Abnormal echocardiogram in 85%.⁵
- If transthoracic echocardiogram is normal and endocarditis is still suspected, order a transesophageal echo.⁶ **SOR A**

DIFFERENTIAL DIAGNOSIS

Fever without a clear cause may be seen with:

- Connective tissue disorders—Typically with other signs depending on the disorder, negative blood cultures, normal echocardiogram.
- Fever of unknown origin—Negative blood cultures or positive cultures with atypical organisms, normal echocardiogram in noncardiac causes.

FIGURE 50-5 Janeway lesions on the palm of a woman hospitalized with acute bacterial endocarditis. These were not painful. (Courtesy of David A. Kasper DO, MBA.)

FIGURE 50-6 Osler node causing pain within pulp of the big toe in the same woman hospitalized with acute bacterial endocarditis. (Osler nodes are painful—remember “O” for Ouch and Osler.) Note the multiple painless flat Janeway lesions over the sole of the foot. (Courtesy of David A. Kasper DO, MBA.)

- Intraabdominal infections—Fever and positive blood cultures, normal echocardiogram.

Echocardiogram findings similar to bacterial endocarditis may be seen with:

- Noninfective vegetations—No fever and negative blood cultures.
- Cardiac tumors—Embolitic complications, right or left heart failure, often located off valves in cardiac chambers, negative blood cultures.
- Cusp prolapse—No fever and negative blood cultures.
- Myxomatous changes—Extra connective tissue in the valve leaflets.
- Lamb excrescences—Stranding from wear and tear on the valve, most commonly aortic, no fever, and negative blood cultures.

MANAGEMENT

- Draw blood cultures (two to three sets) and admit suspected cases to the hospital for IV antibiotics.
- Start antibiotics empirically (SOR C) for specific regimens).

MEDICATIONS

- Cover *Streptococcus* in native valve endocarditis: penicillin G 12 to 18 million units divided every 4 hours and gentamicin 1.5 mg/kg loading dose, then 1 mg/kg every 8 hours.
- Cover *Staphylococcus* in IV drug abusers: nafcillin 2 g every 4 hours and gentamicin; use vancomycin instead of nafcillin when concerned about methicillin-resistant *Staphylococcus aureus* (MRSA) (prior history of MRSA infection).
- Cover MRSA in prosthetic valve endocarditis: vancomycin 30 mg/kg per day divided every 8 hours and gentamicin.
- Alter antibiotics based on culture results. SOR A
- Treat Gram-positive with a β -lactam; current evidence does not support adding an aminoglycoside.⁷ SOR A
- Surgical consultation.
- Surgical excision of infected tissue has a 10% to 16% mortality rate in the immediate post-op period.^{8,9} Consider surgical consultation when:
 - Congestive heart failure is severe with mitral or aortic regurgitation.
 - Fever and/or bacteremia persist for 7 to 10 days despite adequate antibiotic therapy, abscesses or perivalvular involvement occurs, or fungal organisms are identified.
 - Embolic events recur on adequate antibiotic therapy or the risk of embolic events is high because of vegetations larger than 10 mm. SOR C
- Anticoagulation and aspirin are not indicated for infective endocarditis and are contraindicated with cerebral complications or aneurysms.

PREVENTION

- Bacterial endocarditis is a serious life-threatening disease requiring long-term antibiotics and close follow-up.
- Educate patients with high risk for endocarditis of the importance of prophylactic antibiotics before certain procedures. Following are the 2007 American Heart Association recommendations:¹⁰

- Prescribe prophylactic antibiotics only to patients at the highest risk: SOR B
 - Patients with prosthetic cardiac valves.
 - Patients with previous bacterial endocarditis.
 - Cardiac transplant recipients with cardiac valvuloplasty.
 - Patients with these congenital heart defects (CHDs): unrepaired cyanotic CHD, CHD repaired with prosthetic material within the last 6 months, repaired CHD with a residual defect at or adjacent to the site of a prosthetic device.
- Prophylactic antibiotics are *no longer recommended* for patients with mitral valve prolapse.
- Prescribe prophylactic antibiotics only to patients undergoing one of the following:
 - Any dental procedure that involves manipulation of gingival tissue or the periapical region of teeth or perforation of the oral mucosa. SOR C
 - Respiratory procedures involving incision or biopsy of the respiratory mucosa such as a tonsillectomy or adenoidectomy. SOR C
 - Procedures on infected skin or musculoskeletal tissue.
- Endocarditis prophylaxis is *no longer recommended* for patients undergoing gastrointestinal or genitourinary procedures. SOR B
- Prescribe a one-dose regimen to be taken 30 minutes to 1 hour before the procedure:¹⁰
 - Amoxicillin 2.0 g orally for adults, 50 mg/kg for children.
 - Unable to take oral medications: ampicillin 2.0 g IM or IV for adults, 50 mg/kg for children 30 minutes before the procedure; or cefazolin or ceftriaxone 1 g IM or IV for adults, 50 mg/kg for children.
 - Penicillin allergic: clindamycin 600 mg po, IM, or IV for adults; 20 mg/kg po, IM, or IV for children; or azithromycin or clarithromycin 500 mg po for adults, 15 mg/kg po for children. If allergy to penicillin is *not* anaphylaxis, angioedema, or urticaria, may also use cephalexin 2.0 g po for adults, 50 mg/kg po for children; or cefazolin or ceftriaxone 1 g IM or IV for adults, 50 mg/kg for children.

PROGNOSIS

Bacterial endocarditis requires early detection and aggressive antibiotic therapy to decrease mortality.

- Thirty-day mortality is 16% to 25%.³
- Ninety-day mortality is 14.5%.³
- Greater than 6-month mortality is 20% to 37%.³

FOLLOW-UP

- Most patients with bacterial endocarditis will require 4 to 6 weeks of IV antibiotics.
- Depending on the antibiotics, some patients will need to have medication levels monitored.
- Repeat blood cultures to ensure response to therapy.
- An echocardiogram at the end of treatment provides baseline imaging, as patients with endocarditis are at risk for another episode.⁶ SOR C

PATIENT EDUCATION

- Bacterial endocarditis is a serious disease with a significant mortality rate.
- Finish all antibiotics and keep follow-up appointments to ensure adequate treatment.
- Mortality remains elevated even 6 months after an episode.
- Recurrence is common, especially if risk factors remain (i.e., continued immunosuppression or IV drug use).

SECTION 2 PERIPHERAL

51 CLUBBING

Heidi Chumley, MD

PATIENT STORY

A 31-year-old man with congenital heart disease has had these clubbed fingers since his childhood (**Figures 51-1** and **51-2**). A close view of the fingers shows a widened club-like distal phalanx. He has learned to live with the limitations from his congenital heart disease and his fingers do not bother him at all.

INTRODUCTION

Clubbing is a physical examination finding first described by Hippocrates in 400 BC. Clubbing can be primary (pachydermoperiostosis or hypertrophic osteoarthropathy) or secondary (pulmonary, cardiac, or GI disease or HIV). Diagnosis is clinical based on nail fold angles and phalangeal depth ratios. The treatment is to correct the underlying cause, after which clubbing may resolve.

SYNONYMS

Hippocratic nails or fingers, drumstick fingers.

EPIDEMIOLOGY

Prevalence in the general population is unknown:

- Two percent of adult patients admitted to a Welsh general medicine or surgery service.¹
- Thirty-eight percent and 15% of patients with Crohn disease and ulcerative colitis, respectively.²
- Thirty-three percent and 11% of patients with lung cancer and chronic obstructive pulmonary disease (COPD), respectively.³

ETIOLOGY AND PATHOPHYSIOLOGY

- The etiology of clubbing is poorly understood.
- Increased connective tissue growth and angiogenesis in the nail bed result in the remodeling of the finger into a club shape.
- Current explanations include megakaryocyte release of platelet-activated growth factor, hypoxia, vasodilators in circulation, a neurocirculatory mechanism, and chronic activation of macrophages with production of profibrotic factors.⁴

FIGURE 51-1 Clubbing of all the fingers in a 31-year-old man with congenital heart disease. Note the thickening around the proximal nail folds. (Courtesy of Richard P. Usatine, MD.)

FIGURE 51-2 Close-up view of a clubbed finger. (Courtesy of Richard P. Usatine, MD.)

RISK FACTORS

- Family history.
- History of a disease associated with clubbing.

DIAGNOSIS

CLINICAL FEATURES

- History of present illness: Gradual onset of painless enlargement at the ends of the fingers and toes.
 - Family history suggests primary hypertrophic osteoarthropathy/familial clubbing.
 - Social history to identify exposure to asbestos, coal mine dust, and pigeons; tobacco use as risk factor for lung cancer; HIV and tuberculosis risk factors.
- Review of systems: Constitutional, pulmonary, GI, and musculoskeletal symptoms for clues to an underlying disease.⁵

PHYSICAL EXAMINATION

- Abnormal nail fold angles⁶ (**Figure 51-3**).
 - Profile angle (ABC) ≥ 180 degrees.
 - Hyponychial (ABD) ≥ 192 degrees.
 - Phalangeal depth ratio ($BE:GF$) ≥ 1 ⁶ (**Figure 51-3**).
- Schamroth sign, obliteration of the diamond shape normally created when dorsal surfaces of 2 corresponding fingers are opposed (**Figure 51-4**). LR+ (likelihood ratio) 7.60 to 8.40 and LR– 0.14 to 0.25.⁷

TYPICAL DISTRIBUTION

- Bilateral; involves all fingers and often toes.
- Rarely unilateral or involving only one or some digits (consider neurologic or traumatic insult to extremity).

LABORATORY TESTING

Laboratory testing is useful to evaluate for secondary causes. Consider:

- HIV testing if risk factors present.
- Complete blood count (CBC) and blood cultures if systemic symptoms (fever, night sweats, weight loss) are present.
- Thyroid-stimulating hormone (TSH)/thyroxine (T_4) if exophthalmos or pretibial myxedema is present.
- Liver function tests (LFTs), hepatitis serologies for right upper quadrant (RUQ) tenderness or jaundice.

IMAGING

- Screening chest radiograph if an underlying cause is not identified.
- Plain radiograph of the hand can distinguish clubbed from non-clubbed by measuring nail bed greater than or equal to 3 mm.⁸

DIFFERENTIAL DIAGNOSIS

PRIMARY CLUBBING

- Hypertrophic osteoarthropathy (HOA)—Clubbing, periostosis, and arthritis or arthralgias.

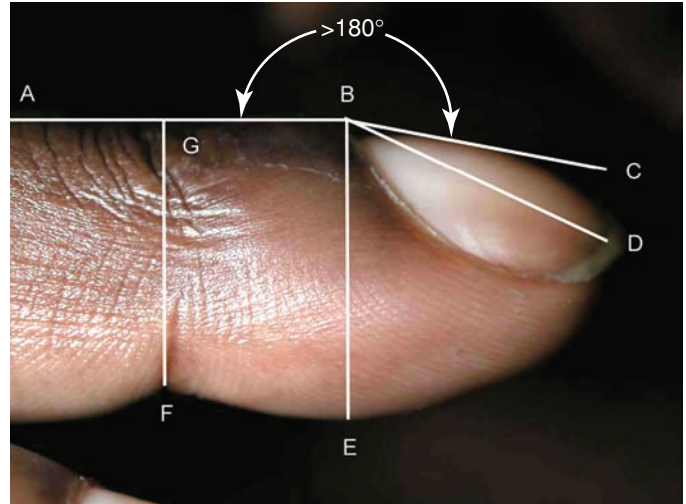

FIGURE 51-3 Clubbing of fingers in a 55-year-old man with chronic obstructive pulmonary disease. Abnormal profile angle (ABC) and hyponychial angle (ABD); distal phalangeal depth (BE) greater than interphalangeal depth (GF). (Courtesy of Richard P. Usatine, MD.)

FIGURE 51-4 Schamroth sign. Loss of the normal diamond shape formed when right and left thumbs are opposed in a person with clubbing of the fingers. (Courtesy of Richard P. Usatine, MD.)

- Primary HOA, also known as pachydermoperiostosis, is an autosomal dominant disorder.
- Secondary HOA is often associated with pulmonary neoplasms.
- Familial clubbing, now thought to be an incomplete form of primary HOA.

SECONDARY CLUBBING

Secondary clubbing can be caused by many conditions, including:⁵

- Pulmonary—Idiopathic pulmonary fibrosis, malignancy, asbestosis, COPD, and cystic fibrosis.
- Cardiac—Congenital heart disease, endocarditis, atrioventricular malformations, or fistulas.
- GI—Inflammatory bowel disease, cirrhosis, and celiac disease.
- HIV infection—Clubbing was found in 36% of patients with HIV in one study.⁹

MANAGEMENT

- Clubbing improves with the management of the underlying disease.²
- Evaluate patients without an obvious associated disease for lung cancer.⁵ **SOR C**
- Evaluate patients with COPD and a phalangeal depth ratio greater than 1 for lung cancer.³ (LR 3.9) **SOR B**

PROGNOSIS

Prognosis depends on the underlying process. Clubbing usually completely reverses after successful treatment of the underlying process.

FOLLOW-UP

Follow-up is dependent on the underlying disease process.

PATIENT EDUCATION

Clubbing may be secondary to many different types of disease, some very serious.

PATIENT RESOURCES

- Medline Plus—<http://www.nlm.nih.gov/medlineplus/ency/article/003282.htm>.

PROVIDER RESOURCES

- Spicknall, et al.⁵ provide an algorithm useful in identifying the underlying cause of clubbing.

52 VENOUS INSUFFICIENCY

Maureen K. Sheehan, MD, MHA

PATIENT STORY

A 45-year-old woman presents to her physician's office with complaints of heaviness and fatigue in her legs (**Figure 52-1**). She does not experience the symptoms in the morning but they become more noticeable as the day progresses and with prolonged standing. When she stands for many hours, she develops swelling in both of her legs. The symptoms are concentrated over her medial calf where she has prominent tortuous veins. She first noted the veins approximately 20 years ago when she was pregnant. Initially, they did not cause her any discomfort but have progressively enlarged now and over the past 10 years have become increasingly painful. She recalls that her mother had similar veins in her legs.

INTRODUCTION

Venous insufficiency, or improperly functioning valves in the venous system, can lead to variety of symptoms, including, but not limited to, heaviness and/or swelling in the legs with prolonged standing, leg fatigue or aching, bleeding from leg varices, skin changes, and ulcerations. The prevalence is higher in industrialized nations and ranges from 15% to 30% of the U.S. population.

SYNONYMS

Varicose veins, venous stasis

EPIDEMIOLOGY

- Varies by definition and region, but generally venous insufficiency affects 27% of the population.¹
- Prevalence estimates vary by some reports, indicating a prevalence of 10.4% to 23% in men and 29.5% to 39% in women.^{2,3}
- More frequent in women as compared to men.
- Symptomatic in more than two-thirds of those affected.
- Varicose veins are notable only in half of patients with venous insufficiency.⁴

ETIOLOGY AND PATHOPHYSIOLOGY

- Most frequently it is a result of valvular dysfunction.
- Valvular dysfunction may be primary or secondary (result of trauma, deep venous thrombosis [DVT], or May-Thurner syndrome).
- It may affect deep system (i.e., femoral veins), superficial system (i.e., saphenous vein), or both.

FIGURE 52-1 Uncomplicated varicose veins of thigh. (Courtesy of Maureen K. Sheehan, MD.)

- The superficial system is involved in 88% of cases either alone or in conjunction with the deep system.
- Dysfunction leads to loss of compartmentalization of veins, leading to distention and increased pressure (**Figures 52-1** and **52-2**).
- Increased pressure in veins is transmitted to microvasculature leading to basement membrane thickening, increased capillary elongation, and visual skin changes (**Figures 52-3** and **52-4**).

RISK FACTORS

- Family history.
- Deep venous thrombosis.
- Female gender.
- Estrogen increase (hormone replacement, pregnancy, oral contraceptive pills).
- Age.
- Obesity.
- Prolonged standing.

DIAGNOSIS

SYMPTOMS

- Heaviness, fatigue, and edema; not present immediately in the morning; gets worse with prolonged standing or walking; relieved with elevation.

TYPICAL DISTRIBUTION

- Varicose veins can be present anywhere on the leg depending upon affected segments or branches; ulcers from venous disease tend to be near the medial malleoli (**Figure 52-5**).

TESTS

- Duplex scanning to assess valve closure; normal valve closure takes 0.5 to 1.0 seconds.

DIFFERENTIAL DIAGNOSIS

- Arterial ulcers—Tend to be at toes, shin, and pressure points (heels or sides of feet).
- Diabetic ulcers—Occur at ambulatory pressure points, mostly at first metatarsal head.
- Malignancy (basal cell or squamous cell carcinoma).
- Chronic infectious diseases (osteomyelitis, leprosy).
- Vasculitides—Irregular border, black necrosis, erythema, or bluish or purplish discoloration of adjacent tissue.

MANAGEMENT

- Graduated compression hose for superficial or deep system insufficiency: **SOR C**

FIGURE 52-2 Varicose veins of posterior calf without hemosiderin deposition, lipodermatosclerosis, or ulceration. (Courtesy of Maureen K. Sheehan, MD.)

FIGURE 52-3 Lipodermatosclerosis with hemosiderin deposition. (Courtesy of Maureen K. Sheehan, MD.)

- 15 to 20 mm Hg—Minor reflux and minimal symptoms.
- 20 to 30 mm Hg—Moderate to severe reflux and symptoms; moderate edema; postsurgical.
- 30 to 40 mm Hg—Severe reflux and symptoms; severe edema.
- Compression for open ulcer.⁵ **SOR B**
- Compression hose treat symptoms, not underlying pathophysiology. Effective only when being worn.
- Surgical intervention is available either with endovenous ablation or with stripping and ligation if superficial system involved.
- If only deep system involvement, then compression hose is the mainstay of therapy. **SOR C**
- When superficial and deep systems are affected, treatment of superficial system leads to improvement of deep system reflux in one-third of the patients.
- A study randomizing patients to stripping and ligation versus compression therapy demonstrated an improved quality of life in the surgical arm.⁷ **SOR A**
- Endovenous therapy uses radiofrequency or laser energy to ablate vein. Because the vein is usually accessed with a needle under ultrasound guidance, an incision is avoided in most instances.
- Decreased postoperative pain and analgesic use in patients undergoing endovenous ablation compared to those undergoing stripping and ligation.⁸ **SOR A**
- Adjunctive phlebectomies or sclerotherapy for branch varicosities may be necessary with either operative approach.

PREVENTION

Patients at risk for developing venous insufficiency (genetics, occupations with prolonged standing, etc.) may benefit from compression hose use.

PROGNOSIS

Majority of patients with venous insufficiency live a full and complete life without significant sequelae. Those with only superficial involvement tend to have greater relief with treatment than those with superficial and deep or only deep system involvement. Most patients obtain relief from interventions such as compression hose or surgery.

FOLLOW-UP

- It depends on the treatment and severity of disease.
- Unna boots for ulceration need to be changed at least weekly.
- Compression hose needs to be replaced every 6 months.
- Following surgical intervention, follow-up depends upon intervention. Stripping and ligation require wound checks, whereas endovenous ablations require ultrasound monitoring.

FIGURE 52-4 Healed ulcers with hemosiderin deposition. (Courtesy of Maureen K. Sheehan, MD.)

FIGURE 52-5 Venous stasis ulcer in the typical location around the medial malleolus. (Courtesy of Maureen K. Sheehan, MD.)

PATIENT EDUCATION

Venous insufficiency is not merely a cosmetic concern. Longstanding disease can give rise to skin changes (**Figures 52-3** and **52-4**) and ulcers (**Figure 52-5**). Compliance with compression hose is necessary. Compression hose only treats symptoms, not the underlying disease process. Even after surgical intervention, new varicose veins may appear as the process is chronic.

53 PNEUMONIA

Mindy A. Smith, MD, MS

PATIENT STORY

Max is a 65-year-old man who presents with a “terrible cough” and fever of several days’ duration. He has just returned from a business trip and is feeling quite run down. His cough is productive with rusty colored sputum. He is otherwise healthy and is a nonsmoker. His chest x-ray is similar to the one shown in **Figure 53-1**. He is diagnosed with probable bacterial pneumonia and is placed on antibiotics. You note that he has never had vaccinations against influenza or pneumococcus and you offer these to him at a follow-up visit when he is well.

INTRODUCTION

Pneumonia refers to an infection in the lower respiratory tract (distal airways, alveoli, and interstitium of the lung). Community-acquired pneumonia (CAP) has traditionally referred to pneumonia occurring outside of the hospital setting. More recently, a subgroup of CAP has been identified that is associated with healthcare risk factors (e.g., prior hospitalization, dialysis, nursing home residence, immunocompromised state); this form of pneumonia has been classified as a healthcare-associated pneumonia (HCAP), although definitions of HCAP vary. While severity and excess mortality are associated with HCAP, as well as a slight increase in multidrug resistant (MDR) pathogens, most studies do not support either a causal relationship between MDR and excess mortality or demonstrate benefit from broad-spectrum antibiotic coverage.¹ It is likely that excess mortality is a result of underlying patient-related factors (e.g., older age, comorbidities, higher initial severity).^{1,2}

EPIDEMIOLOGY

- Three to 4 million adults per year in United States are diagnosed with CAP (8 to 15 per 1000 persons/year).^{3,4}
- Annual incidence rate of CAP requiring hospitalization: 267 per 100,000 population and 1012 per 100,000 individuals older than 65 years of age.⁵
- Ten percent to 20% of patients are admitted to the hospital.^{3,4,6} Of those, 10% to 20% are admitted to the intensive care unit (ICU).⁷
- Increased incidence in men and in blacks versus whites.³
- CAP is the most frequent cause of death caused by infectious disease in the United States and the eighth leading cause of death overall (2007).^{7,8}
- Economic burden associated with CAP is estimated at more than \$12 billion annually in the United States.⁷

FIGURE 53-1 Chest x-ray (CXR) showing right upper lobe consolidation. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York, NY: McGraw-Hill; 2006:218, Figure 5-1 B. Copyright 2006.)

ETIOLOGY AND PATHOPHYSIOLOGY³

- In a study of children hospitalized with CAP (N = 254), the cause of the disease (identified in 85% of cases) was most often viral (62%, with 30% having evidence of both viral and bacterial pathogens).⁹ The most common pathogens were *Streptococcus pneumoniae* (37%), respiratory syncytial virus (29%), and rhinovirus (24%). Dual bacterial infections were found in 19 patients; only 1 patient of 125 tested had a positive blood culture.
- In a single U.S. hospital study, pathogens identified in adult patients with CAP separate from HCAP (N = 208) were *S. pneumoniae* (40.9%), *Haemophilus influenzae* (17.3%), *Staphylococcus aureus* (13.5%) and methicillin-resistant *S. aureus* (MRSA, 12%).¹⁰ For HCAP, the most common pathogens were MRSA (30.6%) and *Pseudomonas aeruginosa* (25.5%). This distribution of pathogens for HCAP may be unique to this setting.
- Most common route of infection is microaspiration of oropharyngeal secretions colonized by pathogens. In this setting, *S. pneumoniae* and *H. influenzae* are the most common pathogens.
- Pneumonia secondary to gross aspiration occurs postoperatively or in those with central nervous system disorders; anaerobes and Gram-negative bacilli are common pathogens.
- Hematogenous spread, most often from the urinary tract, results in *Escherichia coli* pneumonia, and hematogenous spread from intravenous catheters or in the setting of endocarditis may cause *S. aureus* pneumonia.
- *Mycobacterium tuberculosis* (TB), fungi, *Legionella*, and many respiratory viruses are spread by aerosolization. Reported incidence rates of atypical pathogens vary greatly; for example, *Legionella* species were identified in patients with CAP in 1.3% (defined as positive urine antigen),¹⁰ 1.4% (defined as 4-fold rise in antibody titer or a single titer of ≥ 400),¹¹ and 18.9% (defined as 4-fold rise in antibody titer of 128),¹² with coinfection with another pathogen in approximately 10%.
- Etiology is unknown in up to 70% of cases of CAP.

RISK FACTORS^{3,4,13}

- Age older than 70 years (relative risk [RR], 1.5 vs. 60- to 69-year-olds).
- Smoking more than 20 cigarettes/day (odds ratio [OR], 2.77; 95% confidence interval [CI], 1.14 to 6.7)
- Alcohol consumption (RR, 9).
- Asthma (RR, 4.2), chronic bronchitis (OR, 2.22; 95% CI, 1.13 to 4.37), and other chronic lung diseases or pulmonary edema.
- Previous respiratory infection (OR, 2.73; 95% CI, 1.75 to 4.26).
- Uremia.
- Immune suppression (RR, 1.9).
- Malnutrition.
- Acid-suppressing drugs (proton pump inhibitors and histamine-2 receptor antagonist; OR, 1.27; 95% CI, 1.11 to 1.46 and OR, 1.22; 95% CI, 1.09 to 1.36, respectively).¹⁴

FIGURE 53-2 CT scan of the patient in **Figure 53-1** demonstrating a confluent region of lung consolidation with ground-glass opacification on the margins of the consolidated lung commonly seen in bacterial pneumonia. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York, NY: McGraw-Hill; 2006:218, Figure 5-1 C. Copyright 2006.)

DIAGNOSIS

The history can provide clues to the likely pathogen³:

- Alcoholism—Consider *S. pneumoniae*, *Klebsiella*, *S. aureus*, and anaerobes.
- Chronic obstructive pulmonary disease—Consider *S. pneumoniae*, *H. influenzae*, and *Moraxella*.
- Uncontrolled diabetes mellitus—Consider *S. pneumoniae* and *S. aureus*.
- Sickle-cell disease—Consider *S. pneumoniae*.
- HIV with low CD4 count—Consider *S. pneumoniae*, *Pneumocystis carinii*, *H. influenzae*, *Cryptococcus*, and TB.

CLINICAL FEATURES

- Constellation of symptoms includes cough, fever, chills, pleuritic chest pain, and sputum production. Patients may also complain of fatigue, myalgia, and headache.⁴ Patients with viral or atypical pathogens (e.g., *Mycoplasma*, *Chlamydia*) often present with fever, nonproductive cough, and constitutional symptoms developing over several days; patients with *Legionella* pathogens may present initially with GI symptoms.⁴
- Signs include increased respiratory rate, dullness to percussion, bronchial breathing, egophony, crackles, wheezes, and pleural-friction rub. Lung findings in atypical pneumonia may be more diffuse.

LABORATORY STUDIES

- Sputum Gram stain may be helpful in determining etiology in hospitalized patients. Pretreatment Gram stain and culture of expectorated sputum should be performed only if a good-quality specimen is obtained; indications are the same as for blood cultures listed below.¹⁵ An adequate specimen has a more than 25 white blood cells (WBCs) and less than 10 epithelial cells per high-powered field. For intubated patients with severe CAP, an endotracheal aspirate sample should be obtained.¹⁵
- Testing of induced sputum has established merit primarily for detection of TB and *P. carinii*. **SOR A** Special stains are needed for detecting TB, *P. carinii*, and fungi.
- Blood cultures are not recommended routinely for nontoxic, fully immunized children with CAP managed in the outpatient setting.¹⁶ **SOR B** Blood cultures should be obtained in children who fail to demonstrate clinical improvement, and in those who have progressive symptoms or clinical deterioration after initiation of antibiotics.¹⁶ **SOR B**
- Blood cultures are recommended for children requiring hospitalization for presumed bacterial CAP that is moderate to severe, particularly those with complicated pneumonia.¹⁶ **SOR C**
- Routine diagnostic tests to identify an etiologic agent are optional for adult outpatients with CAP.¹⁵ **SOR C** Blood cultures should be considered in ambulatory patients with a temperature higher than 38.5°C (101.3°F) or lower than 36°C (96.8°F) and in those who are homeless or abusing alcohol.³ **SOR C**
- Blood cultures (2 sets prior to administration of antibiotics) are suggested for hospitalized patients who meet clinical indications (i.e., cavitory infiltrates, leukopenia, active alcohol abuse, chronic

severe liver disease, asplenia, positive pneumococcal urinary antigen, or pleural effusion) or are admitted to the ICU.¹⁵ **SOR A** Blood cultures are positive in 6% to 20% of hospitalized patients.³ Investigators in a Canadian study found that blood cultures had limited usefulness in the routine management of patients admitted to the hospital with uncomplicated CAP; only 1.97% (15 of 760 patients) had a change of therapy directed by blood culture results.¹⁷

- Sensitive and specific tests for the rapid diagnosis of influenza virus and other respiratory viruses should be used in the evaluation of children with CAP.¹⁶ A positive influenza test may decrease both the need for additional diagnostic studies and antibiotic use, while guiding appropriate use of antiviral agents in both outpatient and inpatient settings.¹⁶ **SOR A** Serology (4-fold rise in immunoglobulin [Ig] M titer) may also be useful in diagnosing *Mycoplasma pneumoniae*, *Chlamydia pneumoniae*, *Legionella pneumoniae*, *Legionella pneumophila*, and other viral pneumonia.¹⁵ **SOR C**
- Urinary antigens may be useful in diagnosing Legionnaires disease (*L. pneumophila*) and *S. pneumoniae*, and are recommended in patients with severe CAP.¹⁵ **SOR B** Urinary antigen detection tests are not recommended for the diagnosis of pneumococcal pneumonia in children as false-positive tests are common.¹⁶
- Procalcitonin, a peptide precursor of calcitonin used as a biomarker of bacterial infection and sepsis, has been used in the emergency room setting to distinguish between pneumonia (increased level) and an exacerbation of asthma.¹⁸ In one study, use of guidelines including measurement of procalcitonin versus standard guidelines in patients with lower respiratory infection reduced exposure to antibiotics (mean duration: 5.7 vs. 8.7 days).¹⁹
- Pulse oximetry should be performed in patients with pneumonia and suspected hypoxemia. The presence of hypoxemia should guide decisions regarding site of care and further diagnostic testing. **SOR B**

IMAGING

Routine chest x-ray (CXR) is not necessary for the confirmation of suspected CAP in children who are well enough to be treated in the outpatient setting (after evaluation in the office, clinic, or emergency department setting).¹⁶ **SOR A** CXR, posteroanterior and lateral, should be obtained in patients with suspected or documented hypoxemia, significant respiratory distress, those who failed initial antibiotic therapy, and hospitalized patients. **SOR B**

The diagnosis of pneumonia in adults based on clinical history and examination is only 47% to 69% sensitive and 58% to 75% specific, thus CXR is considered a standard part of evaluation.^{3,15} The presence of new infiltrate in conjunction with clinical features is diagnostic.⁶ If the initial CXR is negative in a patient with clinical features of pneumonia, the CXR should be repeated in 24 to 48 hours or a chest CT be considered. **SOR C** Ultrasound may be useful for evaluation of pleural effusion.²⁰

There are 4 general patterns of pneumonia seen on CXR³:

- Lobar—Consolidation involves the entire lobe (**Figures 53-1 to 53-5**). A cavity with an air–fluid level is sometimes seen within the area of consolidation representing abscess formation (**Figure 53-5**).
- Bronchopneumonia—Patchy involvement of one or several lobes that may be extensive (**Figures 53-6 and 53-7**), usually in the dependent lower and posterior lungs (**Figure 53-3**).

FIGURE 53-3 Posteroanterior CXR consolidation in the left lower lobe occupying all 3 basilar segments. There is blunting of the left costophrenic angle indicating a parapneumonic effusion. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York, NY: McGraw-Hill; 2006:219, Figure 5-2 C. Copyright 2006.)

FIGURE 53-4 Lateral CXR of the patient in **Figure 53-3** showing posterior displacement of the major fissure indicating some atelectasis of the left lower lobe. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York, NY: McGraw-Hill; 2006:219, Figure 5-2 D. Copyright 2006.)

- Interstitial pneumonia—Inflammatory process involves the interstitium; usually patchy and diffuse (**Figure 53-8**). A nodular interstitial pattern is seen in patients with histoplasmosis (**Figure 53-9**), miliary TB, pneumoconiosis, and sarcoidosis.
- Miliary pneumonia—Numerous discrete lesions from hematogenous spread (see tuberculosis) (see Chapter 54, Tuberculosis).

DIFFERENTIAL DIAGNOSIS

- Upper respiratory illnesses, including bronchitis, can cause cough, fever, chills, and sputum production with a negative CXR.
- Pulmonary embolus should be considered in patients with pleuritic chest pain or hypoxia and a negative CXR (see Chapter 57, Pulmonary Embolus).
- Asthma can cause cough, wheezing, dyspnea, and hypoxia, with the CXR negative unless mucous plugging causes collapse of airways (see Chapter 55, Asthma).

MANAGEMENT

Initial determination of severity of illness is used to identify patients with CAP who may be candidates for outpatient treatment¹⁵:

- Respiratory rate more than 30 breaths/min without underlying disease is single best predictor.
- British Thoracic Society (BTS) rule—The presence of one or more of the following 4: confusion; blood urea nitrogen greater than 7 mmol/L; respiratory rate greater than 30 breaths/min; systolic blood pressure lower than 90 mm Hg or diastolic blood pressure lower than 60 mm Hg. If none are present, mortality rate is 2.4%; 1 present, 8%; 2 present, 23%; 3 present, 33%; and all 4 present, 80%.
- A number of other severity scores are available (e.g., CURB-65 criteria [confusion, uremia, respiratory rate, low blood pressure, age 65 years or greater] and prognostic models such as the Pneumonia Severity Index),^{4,15} but one study found that the modified BTS performed best, although they recommend validation in each clinical setting.²¹
- Assessment of oxygen consumption/hypoxia.

NONPHARMACOLOGIC

- Based on limited data, chest physiotherapy can't be recommended as part of routine care for adults with pneumonia.²² Positive expiratory pressure (versus no physiotherapy) and osteopathic manipulative treatment (OMT versus placebo therapy) appear to slightly reduce the duration of hospital stay (by 2.02 and 1.4 days, respectively). OMT may also reduce duration of antibiotic use by 1 to 2 days.²²
- The Infectious Diseases Society of America/American Thoracic Society recommend a cautious trial of noninvasive ventilation for patients with hypoxemia or respiratory distress unless they require immediate intubation because of severe hypoxemia (arterial oxygen pressure/fraction of inspired oxygen [$\text{PaO}_2/\text{FiO}_2$] ratio <150) and bilateral alveolar infiltrates.¹⁵

FIGURE 53-5 CXR showing a consolidation in the left upper lobe; note oval lucency that represents cavitation within the infiltrate. This patient had *Klebsiella pneumoniae*. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York, NY: McGraw-Hill; 2006:223, Figure 5-6 A. Copyright 2006.)

- On small randomized controlled trial (RCT) (N = 40) found continuous positive airway pressure (CPAP) delivered by helmet improved oxygenation more quickly than oxygen therapy alone (median: 1.5 vs. 48 hours, respectively) in patients with CAP and moderate hypoxemic acute respiratory failure.²³

MEDICATIONS

Antimicrobial therapy is not routinely required for preschool-age children with CAP because of the high proportion with viral disease.¹⁶ **SOR A** When antibiotics are prescribed, treatment courses of 10 days are recommended.

- Amoxicillin should be used as first-line therapy for previously healthy, appropriately immunized infants and preschool-age children with mild to moderate CAP suspected to be of bacterial origin.¹⁶ **SOR B** A Cochrane review supported use of amoxicillin (or co-trimoxazole) as first-line therapy with amoxicillin clavulanate and cefpodoxime considered as alternative second-line drugs; limited data were available on other antibiotics.²⁴
- Amoxicillin is also recommended for previously healthy, appropriately immunized school-age children and adolescents with mild to moderate CAP with consideration of atypical pathogens.¹⁶ **SOR B** If atypical pathogens are suspected clinically, macrolide antibiotics should be prescribed and diagnostic testing performed.
- Influenza antiviral therapy should be administered as soon as possible (within 48 hours) to children with moderate to severe CAP consistent with influenza virus infection during widespread local circulation of influenza viruses.¹⁶ **SOR B**
- For children with CAP who are inpatients, ampicillin or penicillin G should be administered to the fully immunized infant or school-age child when local epidemiologic data document lack of substantial high-level penicillin resistance for invasive *S. pneumoniae*.^{16,24} Empiric therapy with a third-generation parenteral cephalosporin (ceftriaxone or cefotaxime) should be prescribed for hospitalized infants and children who are not fully immunized, in regions where local epidemiology of invasive pneumococcal strains documents high-level penicillin resistance, or for infants and children with life-threatening infection.¹⁶ **SOR B**
- For children who are inpatients, empiric combination therapy with a macrolide (oral or parenteral) in addition to a β -lactam antibiotic, should be prescribed when *M. pneumoniae* and *C. pneumoniae* are significant considerations; diagnostic testing should be performed.¹⁶ **SOR B** For children hospitalized with severe and very severe CAP, penicillin/ampicillin plus gentamicin is superior to chloramphenicol.²⁴
- Vancomycin or clindamycin (based on local susceptibility data) should be provided in addition to β -lactam therapy for hospitalized children if clinical, laboratory, or imaging characteristics are consistent with infection caused by *S. aureus*.¹⁶ **SOR C**

Empiric antibiotic treatment for adults with CAP includes¹⁵:

- Outpatient, uncomplicated (previously healthy, no risk factors for drug-resistant *S. pneumoniae* [DRSP] infection)—Macrolide (erythromycin, azithromycin, or clarithromycin) **SOR A** or doxycycline. **SOR C** Authors of a Cochrane review did not find sufficient evidence to determine antibiotic choice for the treatment of

FIGURE 53-6 This patient has bilateral pulmonary infiltrates worsening despite antibiotics characteristic of severe bronchopneumonia. Note air bronchograms (arrows) on the right side. He was diagnosed with *Legionella pneumoniae*. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York, NY: McGraw-Hill; 2006:221, Figure 5-4 B. Copyright 2006.)

FIGURE 53-7 CT scan of the patient in Figure 53-6 at the level of the main pulmonary arteries showing extensive pulmonary consolidation in both lungs. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York, NY: McGraw-Hill; 2006:221, Figure 5-4 D. Copyright 2006.)

CAP in ambulatory patients; individual study results did not demonstrate significant differences in efficacy between various antibiotics and antibiotic groups.²⁵

- Outpatient with comorbidities (e.g., cardiac disease, diabetes mellitus) or risk factors for DRSP—Respiratory fluoroquinolone (i.e., levofloxacin [750 mg], moxifloxacin, and gemifloxacin) or β -lactam **plus** macrolide. **SOR A** In regions with high rate (>25%) of macrolide-resistant *S. pneumoniae*, consider use of an alternate agent.
- Hospitalized patient (non-ICU)—Respiratory fluoroquinolone **or** β -lactam (preferred agents include cefotaxime, ceftriaxone, and ampicillin; ertapenem for selected patients) **plus** macrolide combination. **SOR A** Doxycycline can be considered as an alternative to the macrolide. Treatment should be started in the emergency room for patients admitted from there. A Cochrane review, however, did not find benefit in survival or clinical efficacy using empirical atypical coverage (quinolone monotherapy or β -lactams or cephalosporins) in hospitalized patients with CAP.²⁶
- If the etiology of CAP is identified on the basis of reliable microbiologic methods, antimicrobial therapy should be directed at that pathogen.
- Early treatment (within 48 hours of the onset of symptoms) with oseltamivir or zanamivir is recommended for influenza A.¹⁵
- Duration of therapy—A minimum of 5 days. **SOR A** The patient should be afebrile for 48 to 72 hours and have no more than 1 CAP-associated sign of instability (e.g., temperature higher than 37.8°C [100°F], tachycardia, respiratory rate >24 breaths/min, hypotension, oxygen saturation <90%, unable to maintain oral intake, altered mental status) before discontinuing antibiotics.¹⁵
- Dexamethasone reduced hospital length of stay (LOS) by about 1 day when added to antibiotic treatment in nonimmunocompromised patients with CAP.²⁷ There were no differences in in-hospital mortality or severe adverse events in this study. Among children hospitalized with CAP, adjunctive steroids also appears to reduce hospital stay but only in conjunction with concomitant β -agonist therapy (i.e., likely only children with acute wheezing benefit).²⁸ Steroid use increased LOS and readmission when used in patients who did not receive concomitant β -agonist therapy.

HOSPITALIZATION

- Children and infants who have moderate to severe CAP, as defined by several factors including respiratory distress and hypoxemia, should be hospitalized for management, including skilled pediatric nursing care.¹⁶ **SOR A**
- Infants younger than 3 to 6 months of age with suspected bacterial CAP, children and infants with suspected or documented CAP caused by a pathogen with increased virulence (e.g., community-acquired MRSA), and children and infants for whom there is concern about careful observation at home or who are unable to comply with therapy or follow-up are likely to benefit from hospitalization.¹⁶ **SOR C**
- For adults, severity-of-illness scores can be used to identify patients with CAP who may be candidates for outpatient treatment. **SOR A** Consider hospitalization if the patient has severe CAP (CURB-65 ≥ 2 or BTS score >0) or has hypoxia, worsening symptoms, preexisting conditions that compromise safety of home care or for patients who fail to improve in more than 72 hours.^{3,15}

FIGURE 53-8 CXR showing basilar predominant interstitial lung disease in this 70-year-old woman; given her age, idiopathic pulmonary fibrosis is the most likely diagnosis. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York, NY: McGraw-Hill; 2006:81, Figure 3-10 A. Copyright 2006.)

FIGURE 53-9 Nodular interstitial pattern with many calcified granulomas in a patient with histoplasmosis. (From Schwartz DT, Reisdorff EJ. *Emergency Radiology*. New York, NY: McGraw-Hill; 2000:460, Figure 17-15. Copyright 2000.)

PREVENTION

- Vaccination—Children should be immunized with vaccines for bacterial pathogens including *S. pneumoniae*, *H. influenzae* type b, and pertussis to prevent CAP.¹⁶ **SOR A** The use of pneumococcal conjugate vaccine is associated with an overall decreased incidence of invasive disease among children younger than 5 years of age (from approximately 99 cases per 100,000 population [1998–1999] to 21 cases per 100,000 population [2008]).²⁹ Pneumococcal polysaccharide vaccine is recommended for persons 65 years of age and older, and for those with selected high-risk concurrent diseases.¹⁵ **SOR B** All infants 6 months of age or older, children, adolescents, persons 50 years of age or older, others at risk for influenza complications, and healthcare workers should be immunized annually with vaccines for influenza virus to prevent CAP.^{15,16} **SOR A** Vaccination status should be assessed at the time of hospital admission for all patients and appropriate vaccines offered at discharge.¹⁵ **SOR C**
- Smoking cessation assistance should be offered to patients who smoke (see Chapter 236, Tobacco Addiction).
- To prevent spread of respiratory pathogens, respiratory hygiene measures should be practiced.¹⁵ These include the coughing into the elbow and use of hand hygiene and masks or tissues for patients with cough, particularly in outpatient settings and emergency departments.

PROGNOSIS

- Patients on adequate therapy for CAP should demonstrate clinical (and laboratory) signs of improvement within 48 to 72 hours.¹⁶
- Outpatient mortality rate is 1%. The mortality rate for those who require admission to the hospital averages 12%, and the mortality rate for patients with severe CAP in the ICU setting approaches 40%.³ In a multihospital study in Canada, 9% (N = 89) of patients died in-hospital, 10% died at 30 days, and 247 (26%) died by 1 year. In-hospital mortality was higher among patients with admission hypoglycemia.³⁰
- Using a large database, guideline concordant therapy for CAP (65% of cases) was associated with decreased in-hospital mortality (OR, 0.70; 95% CI, 0.63 to 0.77), sepsis (OR, 0.83; 95% CI, 0.72 to 0.96), renal failure (OR, 0.79; 95% CI, 0.67 to 0.94), and reduced hospital LOS and duration of parenteral therapy (0.6 days for both).³¹

FOLLOW-UP

- Assess need and provide pneumococcal and influenza vaccination at hospital discharge or follow-up.
- Monitor improvement and treat comorbid illness (which may worsen).
- In children, repeat CXRs (inpatient or outpatient) are not routinely required if recovery from an episode of CAP is uneventful.¹⁶ **SOR B** Follow-up chest radiographs should be obtained in patients with complicated pneumonia with worsening respiratory distress or clinical instability, or in those with persistent fever that is not

responding to therapy over 48 to 72 hours. **SOR C** Repeat CXR at 4 to 6 weeks after the diagnosis of CAP should be obtained in patients with recurrent pneumonia involving the same lobe and in patients with lobar collapse at initial CXR with suspicion of an anatomic anomaly, chest mass, or foreign-body aspiration.¹⁶ **SOR B**

- In adults, repeat CXRs until clear if the patient is older than 40 years or smokes as 2% of them may have underlying cancer.³

PATIENT EDUCATION

- Patients who smoke should be offered cessation assistance.
- Improvement is expected in healthy outpatients younger than age 65 years in 48 to 72 hours with their returning to work or school in approximately 4 to 5 days and complete improvement within 2 weeks.
- In hospitalized patients, clinical stability is expected in 3 to 7 days; mortality is 12% with 70% developing a complication such as respiratory failure, congestive heart failure, shock, dysrhythmia, myocardial infarction, GI bleeding, or renal insufficiency.³

54 TUBERCULOSIS

Mindy A. Smith, MD, MS

PATIENT STORY

A 20-year-old man from Mexico presents to the emergency room in a South Texas hospital with a persistent cough for 3 weeks, low-grade fever, and night sweats. His chest x-ray shows mediastinal and right hilar lymphadenopathy and right upper lobe consolidation concerning for primary tuberculosis (**Figure 54-1**). Upon review of the radiograph, the emergency room staff admits the patient to a single room with negative pressure. The patient is placed in respiratory isolation, sputum is sent for acid-fast bacillus (AFB) stain and cultures, and the results show acid-fast bacilli consistent with *Mycobacterium* spp. (**Figure 54-2**). While culture results are pending, the patient is started on 4 antituberculosis drugs. Fortunately, the sputum culture result shows *pan susceptible Mycobacterium tuberculosis*, and his treatment continues with directly observed therapy through the local city health department.

INTRODUCTION

Tuberculosis (TB) is a bacterial infection caused by *M. tuberculosis*, an obligate intracellular pathogen that is aerobic, acid fast, and nonencapsulated. TB primarily involves the lungs, although other organs are involved in one-third of cases. Improvements in diagnostics, drugs, vaccines, and understanding of biomarkers of disease activity are expected to change future management of this devastating worldwide disease.

EPIDEMIOLOGY

- More than 8 million cases occur annually around the world, with nearly 2 million TB-related deaths¹; 95% of TB deaths occur in low- and middle-income countries.
- A total of 11,182 TB cases (3.6 per 100,000 persons) were reported in the United States in 2010. This represents the lowest incidence rate since recording began in 1953.² An estimated 2 billion people worldwide have latent TB.³
- The multiple-drug resistant (MDR) TB rate in the United States was 1.2% (88 cases) in 2010; a rate that remains relatively stable in the United States.¹ MDR TB rates are highest in India, China, the Russian federation, South Africa, and Bangladesh.³
- Based on the 2010 data, 60% of reported U.S. cases of *M. tuberculosis* occurred in foreign-born individuals (case rate 11 times higher than U.S.-born individuals).¹
- There were 547 reported deaths from TB in the United States in 2009 (a 7% decrease from 2008).¹
- Prophylactic treatment of those with latent TB (infection without active disease—diagnosed by tuberculin skin test conversion from negative to positive or by an interferon gamma release assay performed on blood) can reduce the risk of active TB by 90% or more.⁴ **SOR A**

FIGURE 54-1 Typical presentation of a primary pulmonary tuberculosis infection in a 20-year-old man. **A.** Frontal chest radiograph shows mediastinal and right hilar lymphadenopathy (*black arrows*) and right upper lobe consolidation (*white arrow*). **B.** Contrast-enhanced CT demonstrates low-density enlarged mediastinal lymph nodes with rim peripheral enhancement consistent with necrotizing lymphadenopathy (*arrows*). (Courtesy of Carlos Santiago Restrepo, MD.)

ETIOLOGY AND PATHOPHYSIOLOGY⁴

- Infection is transmitted by aerosolized respiratory droplet nuclei.
- Approximately 10% of those infected develop active TB, usually within 1 to 2 years of exposure; risk factors for the development of active TB are listed below.
- There are 3 host responses to infection—Immediate nonspecific macrophage and likely neutrophil ingestion of those bacilli reaching the alveoli, later tissue-damaging response (delayed-type hypersensitivity reaction), and specific macrophage activating and potentially neutrophil-related response, the latter, if effective, walling off infection into granulomas. Recent evidence suggests that mycobacteria themselves may promote granuloma formation and these granulomas are dynamic, blurring distinctions between latent and active TB.³
- In areas of high prevalence, TB is often seen in children. The disease process usually localizes to the middle and upper lung zones accompanied by hilar and paratracheal lymphadenopathy (as the tubercle bacilli spread from lung to lymphatic vessels). The primary focus usually heals spontaneously and may disappear entirely or, if encapsulated by fibroblasts and collagen fibers, be visible as a calcified lung nodule (Ghon complex) (**Figure 54-3**).

RISK FACTORS

Risk factors for infection or progression to active TB include²⁻⁴:

- Minority and foreign-born populations (subject to overcrowding and malnutrition).
- HIV (relative risk [RR] for progression to active TB 100) and other immunocompromised states (e.g., cancer, treatment with tumor necrosis factor antagonists) (RR [progression to active TB] 10). As a result of the high susceptibility of HIV-infected patients, 12% of worldwide TB cases are HIV-associated with sub-Saharan Africa accounting for 4 of every 5 of these cases.³
- Chronic diseases such as diabetes mellitus (RR 3) or chronic renal failure/hemodialysis (RR [infection and progression to active TB] 10 to 25 for renal failure).
- Malignancy.
- Genetic susceptibility.
- Bariatric surgery or jejunioileal bypass (RR [progression to active TB] 30 to 60) recipients.
- Injection drug users (RR [progression to active TB] 10 to 30).
- Smoking (RR 2 for progression and infection).
- Personnel who work or live in high-risk settings (e.g., prisons, long-term care facilities, and hospitals).
- Adult women (ratio 2:1 adult man).
- Older age (both infection and progression).
- Children younger than 4 years of age who are exposed to high-risk individuals.
- Recent infection (<1 year) (RR [progression to active TB] 12.9 vs. old infection).

FIGURE 54-2 The acid-fast bacilli of *Mycobacterium tuberculosis* seen with acid-fast staining at 100 power with oil immersion microscopy. (Courtesy of Richard P. Usatine, MD.)

FIGURE 54-3 Primary tuberculosis may coalesce into a small granuloma in the upper lobe referred to as a Ghon complex. (From Miller WT, Jr. *Diagnostic Thoracic Imaging*. New York, NY: McGraw-Hill; 2006:289, Figure 6-5 E,.)

- Fibrotic lung lesions (spontaneously healed) (RR [progression to active TB] 2 to 20).
- Silicosis (RR [infection] 3 and RR [progression to active TB] 30).
- Malnutrition (RR [progression to active TB] 2).
- In a study of hospital personnel, only the percentage of low-income persons within the employee's residential postal zone was independently associated with conversion (odds ratio [OR] 1.39, 95% confidence interval [CI], 1.09 to 1.78).⁵

DIAGNOSIS

The diagnosis of active TB requires a high index of suspicion. In addition, targeted testing for latent TB in vulnerable populations that would benefit from treatment (recent [<5 years] immigrants, immunosuppressed patients, patients with diabetes mellitus and/or chronic renal disease, recent TB or close contact with someone with TB such as household members and healthcare workers) is suggested.⁶ Manifestations of active TB can be classified as pulmonary or extrapulmonary. TB can affect any organ system.

CLINICAL FEATURES

The disease may be asymptomatic (1 in 4 culture-confirmed cases from active case finding in Asia).³

Pulmonary:

- Early nonspecific signs and symptoms: fever, night sweats, fatigue, anorexia, weight loss.
- Later nonproductive cough (lasting 2 to 3 weeks) or cough with purulent sputum.
- Patients with extensive disease may develop dyspnea or acute respiratory distress syndrome.
- Physical examination findings also nonspecific with crackles or rhonchi.

Extrapulmonary TB, caused by hematogenous spread, occurs in the following order of frequency⁴:

- Lymph nodes: painless swelling of cervical and supraclavicular nodes (scrofula) (**Figure 54-4**).
- Pleura: pleural effusion with exudates.
- Genitourinary tract: may cause urethral stricture, kidney damage or infertility (in women, affects the fallopian tubes and endometrium).
- Bones and joints: pain in the spine (Pott disease, **Figure 54-5**), hips, or knees.
- Other less common sites are meninges, peritoneum, intestines, skin, eye, ear, and pericardium.
- TB of the skin (scrofuloderma) shows ulcerations of the skin (**Figures 54-4** and **54-6**) in the inguinal or cervical region along with lymphadenopathy.

SKIN TESTING AND RAPID TESTING

Positive results on either a tuberculin skin test (TST) or an interferon- γ release assay (IGRA) in the absence of active TB establish a diagnosis of latent TB infection.

- TST with purified protein derivative (PPD) is not useful in diagnosing active TB but is used to detect latent infection in exposed or

FIGURE 54-4 Young boy in Africa with scrofuloderma and large cervical and submandibular lymphadenopathy from tuberculosis. (Courtesy of Richard P. Usatine, MD.)

FIGURE 54-5 Pott disease from tuberculosis infection of the spine resulting in a severe kyphoscoliosis. Note to continue skin ulceration on the right and a severe deformity caused by this disease. (Courtesy of Richard P. Usatine, MD.)

high-risk individuals. A positive test is 10 mm induration at the inoculation site or 5 mm induration in a patient who is immunocompromised; evaluated in 48 to 72 hours after test placement.

- Two commercially produced IGRAs are licensed for use in the United States and in many other countries: QuantiFERON-TB Gold (QFT-G, Cellestis Limited, Carnegie, Victoria, Australia) and TSPOT.TB (Oxford Immunotec, Inc; Oxford, England) as an aid for diagnosing *M. tuberculosis* infection.³
- IGRAs detect the release of interferon- γ in fresh heparinized whole blood from sensitized persons when it is incubated with mixtures of synthetic peptides using antigens present in *M. tuberculosis*. Advantages include no need for a return visit and greater specificity than skin testing. Disadvantages include cost, availability, and lack of supporting data that these tests improve patient outcomes.
- IGRAs have limited accuracy in diagnosing active TB in HIV-infected patients and should not be used alone to rule out or rule in disease.⁷ In one study of children investigated for TB in 6 U.K. pediatric centers, TST had a sensitivity of 82%, QuantiFERON-TB Gold in tube (QFT-IT) had a sensitivity of 78% and TSPOT.TB of 66%; combining TST and IGRA results increased sensitivity for both tests (ability to rule out TB).⁸ In practice, IGRA have become standard of care for *M. tuberculosis* screening in some HIV clinics.
- Nucleic acid amplification tests (NAATs) on sputum specimens are under investigation and are being used to confirm diagnosis in some institutions.³

LABORATORY AND ANCILLARY TESTING

- Nonspecific findings include mild anemia and leukocytosis.
- Urinalysis may show “sterile” pyuria and hematuria with urinary tract involvement.
- Acid-fast bacilli may be seen on acid-fast staining from sputum or pleural or peritoneal fluid (**Figure 54-2**). They may also be seen upon staining tissue from fine-needle aspiration or biopsy of lymph nodes or other tissues as above. Sputum processing with bleach or sodium hydroxide and centrifugation and use of fluorescent microscopy is associated with increased sensitivity of smear microscopy.³
- Definitive diagnosis is based on culture of sputum (3 sets of samples collected 8 to 24 hours apart), urine (3 morning specimens—positive in 90% with urinary tract infection), or from tissue or bone biopsy using automated liquid culture systems. *M. tuberculosis* is slow growing and may take 4 to 8 weeks to identify. Authors of a recent review note that one specimen should be tested with NAAT.⁹ Once identified, testing for drug sensitivity should be performed.
- Obtaining baseline liver enzymes is recommended for patients older than age 35 years, or for those with a history of liver disease, HIV infection, pregnancy (or within 3 months postdelivery), concomitant hepatotoxic therapy, or regular alcohol use.
- Testing vision, including color vision, is suggested prior to initiating and throughout treatment with ethambutol, which can cause irreversible cumulative toxicity to the optic nerve.
- Biomarkers of disease activity are an area of active investigation; however, a simple, inexpensive point-of-care test is still not available.

FIGURE 54-6 Young adult man in Africa with scrofuloderma showing an ulcerated lesion on one side and inguinal adenopathy on the other side. (From Schwartz DT, Reisdorff EJ. *Emergency Radiology*. New York, NY: McGraw-Hill; 2006:469, Figure 17-28. Copyright 2006.)

FIGURE 54-7 A 36-year-old man with pulmonary tuberculosis. There is an opacity in the left pulmonary apex associated with a cavity consistent with fibrosis and scarring changes of pulmonary tuberculosis. Also there is an infiltrate in the right lung. (From Schwartz DT, Reisdorff EJ. *Emergency Radiology*. New York, NY: McGraw-Hill; 2006:470, Figure 17-30 (upper block only). Copyright 2006.)

IMAGING

- Chest x-ray (CXR) is the diagnostic test of choice and classically shows upper lobe infiltrates with cavitation and/or lymphadenopathy (**Figures 54-1 and 54-7**).
- Other patterns of TB seen on CXR include a solitary nodule (Ghon complex) (**Figure 54-3**) and diffuse infiltrates that may represent bronchogenic spread (**Figure 54-8**).
- CXR pattern in children and young adults often shows an infiltrate with hilar and paratracheal lymphadenopathy (**Figures 54-1 and 54-9**).
- In disseminated (miliary) TB, innumerable tiny nodules are seen throughout both lungs on CXR and CT (**Figure 54-10**).
- Reactivation TB may show large cavities in both upper lobes associated with bronchiectasis and fibronodular opacities (**Figure 54-11**).
- X-ray, CT, or MRI of bone may show destructive lesions. Spinal MRI has a sensitivity of approximately 100% and specificity of 88% for detecting tuberculous lesions before deformity develops.¹⁰

BIOPSY

Histology reveals granulomas with caseating necrosis.

DIFFERENTIAL DIAGNOSIS

Because any pattern on CXR may be seen with active TB, the differential diagnosis includes:

- Bacterial or viral pneumonia—Sputum or blood culture may reveal the infecting organism, and the patient will usually respond to antibacterial drugs and/or time.
- Fungal respiratory infections—These patients usually have a history of travel to or living in an area where histoplasmosis or coccidiomycosis is endemic.
- Acute histoplasmosis is usually asymptomatic or causes only mild symptoms and CXR typically shows hilar adenopathy with or without pneumonitis (**Figure 54-11**); patients with chronic pulmonary histoplasmosis have gradually increasing cough, weight loss, and night sweats, and CXR shows uni- or bilateral fibronodular, apical infiltrates; positive serology or culture, immunodiffusion test, or lung biopsy can be diagnostic.
- Coccidiomycosis has similar clinical features to TB and CXR may show infiltrate, hilar adenopathy, and pleural effusion; serologic tests are useful in the diagnosis.
- Sarcoidosis—No TB contacts, dyspnea and cough, hilar adenopathy on CXR, skin lesions help differentiate along with serum angiotensin-converting enzyme level or biopsy. Pathology shows noncaseating granulomata (see Chapter 175, Sarcoidosis).

MANAGEMENT

Patients may be managed by their primary care provider, by public health departments, or jointly, but in all cases the health department is ultimately responsible for ensuring availability of appropriate diagnostic and treatment services and for monitoring the results of therapy.

FIGURE 54-8 A 23-year-old woman with pulmonary tuberculosis. There is increased density of the lung parenchyma in the upper left lobe with a heterogeneous pattern showing areas of consolidation, fibrosis and bullae. Other sections of the lung show a micronodular pattern. There is a retraction of the mediastinum toward the left. This whole pattern is consistent with pulmonary tuberculosis. (Courtesy of Richard P. Usatine, MD.)

FIGURE 54-9 Primary tuberculosis in a child; note the left lower lobe infiltrate and the left hilar lymphadenopathy and right paratracheal adenopathy. (From Schwartz DT and Reisdorff EJ. *Emergency Radiology*. New York, NY: McGraw-Hill; 2000:469, Figure 17-28.)

NONPHARMACOLOGIC

- There are insufficient data to support use of free food or nutritional supplements on improving treatment outcome or quality of life in individuals with TB in the United States.¹¹ However, attention to nutrition has shown to be beneficial in a study of TB treatment in Haiti.¹²
- Vitamin D deficiency has been linked to TB susceptibility and there is evidence that vitamin D suppresses intracellular growth of *M. tuberculosis* in vitro. Data are insufficient to determine if vitamin D supplementation is useful as an adjunct to TB treatment. One randomized controlled trial (RCT) found no differences in time to sputum culture conversion with adjunctive vitamin D in the whole study population, but reported a significant hastening of sputum culture conversion in participants with the tt genotype of the TaqI vitamin D receptor polymorphism.¹³ Many experts recommend screening and treatment for vitamin D deficiency in all TB patients. **SOR C**

MEDICATIONS

For adult patients with *active TB* there are 4 major drugs used for treatment. The firstline anti-TB medications should be administered together; split dosing should be avoided. Review the patient's current medications to avoid drug interactions. A few combination medications are available but are more costly. The following regimen is suggested by the American Thoracic Society, Infectious Diseases Society of America, and the Centers for Disease Control and Prevention (2003)¹⁴: **SOR B**

- Two-month initial treatment phase with all 4 medications (isoniazid 5 mg/kg daily [maximum 300 mg] or 15 mg/kg thrice weekly [maximum 900 mg]); rifampin (10 mg/kg daily or thrice weekly [maximum 600 mg]); pyrazinamide (20 to 25 mg/kg daily [maximum 2 g] or 30 to 40 mg/kg thrice weekly [maximum 3 g]); and ethambutol (15 to 20 mg/kg daily or 25 to 30 mg/kg thrice weekly). A RCT found a fixed-dose 4-drug combination was noninferior to treatment with 4 drugs separately.¹⁵
- Four-month continuation phase with isoniazid (INH) and rifampin; treatment is extended to 7 months for patients with cavitary pulmonary TB who remain sputum-positive after initial treatment or if pregnant. The World Health Organization 2010 recommendations agree with continuing rifampin for 6 months and emphasize the importance of drug sensitivity testing to guide individual patient management.¹⁶
- To prevent INH-related neuropathy, pyridoxine 10 to 25 mg/day may be given, especially to those at risk for vitamin B₆ deficiency (i.e., alcoholic, malnourished, pregnant or lactating women, HIV-positive, and those with chronic disease). **SOR A**
- Drug-resistant TB is treated with a variety of injectable drugs including streptomycin, kanamycin, and amikacin, or oral drugs, including fluoroquinolones, ethionamide, cycloserine, and *p*-aminosalicylic acid.⁴ In a Cochrane review of 11 small trials on the use of fluoroquinolones in TB regimens, investigators found no difference in trials substituting ciprofloxacin, ofloxacin, or moxifloxacin for firstline drugs in relation to cure (416 participants, 3 trials), treatment failure (388 participants, 3 trials), or clinical or radiologic improvement (216 participants, 2 trials).¹⁷ Substituting ciprofloxacin into firstline regimens in drug-sensitive TB led to a higher incidence of relapse in HIV-positive patients.

FIGURE 54-10 Disseminated (miliary) tuberculosis with tiny innumerable nodules throughout both lungs. **A.** Chest x-ray. (Courtesy of Richard P. Usatine, MD.) **B.** CT scan. (Courtesy of Carlos Santiago Restrepo, MD.)

- Research into adjuvant immunotherapy (e.g., antitumor necrosis factor therapies) is underway to determine whether this treatment will accelerate the response to treatment.
- In patients with HIV infection, treatment with antiretroviral therapy (ART) should be started during the first 2 to 8 weeks of TB treatment.¹⁶ **SOR B** In a RCT of early ART treatment (2 weeks after initiating TB treatment) versus later (8 weeks after) in patients with TB and HIV, investigators found a significantly reduced risk of death in the earlier ART treatment group (18% vs. 27% in delayed treatment group).¹⁸ Rates of immune reconstitution inflammatory syndrome, however, were higher when starting earlier.
- An open-label RCT in South Africa of patients with TB and HIV (plus CD4+ T-cell count <500 per cubic millimeter) found similar AIDS or death rates in the groups assigned to early ART (within 4 weeks) versus later ART (within the first 4 weeks of the continuation phase) (18 vs. 19 cases, respectively) and also reported higher rates of immune reconstitution inflammatory syndrome when starting earlier (20.1 vs. 7.7 cases/100 person-years).¹⁹ AIDS and death rates were higher, however, for those with very low CD4 counts (<50 per cubic millimeter) randomized to later initiation of ART (26.3 vs. 8.5 cases per 100 person-years).¹⁹
- Treatment may be given daily or intermittently (3 times a week throughout or twice weekly after the initial phase). For patients who are HIV-seronegative with noncavitary pulmonary TB and negative cultures at 2-months, treatment may be given once weekly.

For adult patients with *latent TB*, a treatment decision is made considering the benefits of treatment based on individual's risk for developing TB disease (see Risk Factors above) and the person's level of commitment to completion of treatment and resources available to ensure adherence.²⁰ Persons with no known risk factors for TB may be considered for treatment of latent TB if they have either a positive IGRA result or if their reaction to the TST is 15 mm or larger. The following options are used:

- INH 5 mg/kg daily (maximum 300 mg) for 9 months; **SOR A** twice weekly regimens (15 mg/kg [maximum 900 mg]) may be considered if the patient is under direct observation therapy and 6-month therapy may be considered for adults who are not HIV-infected and have no fibrotic lesions on CXR. **SOR B** The standard treatment regimen is preferred for HIV-infected people taking ART, and children 2 to 11 years of age.
- Rifampin (10 mg/kg daily [maximum 600 mg]) for 4 months if INH-resistant TB or allergy.
- Rifapentine (900 mg; a rifamycin derivative) plus INH (900 mg) for 3 months of directly observed once-weekly therapy. The Centers for Disease Control and Prevention (CDC) recommends this regimen for otherwise healthy patients 12 years of age or older who have latent tuberculosis infection and factors that are predictive of TB developing (e.g., recent exposure to contagious TB).²¹ **SOR A**
- In an open-label, randomized noninferiority trial comparing 3 months of directly observed once-weekly therapy with rifapentine plus INH with 9 months of self-administered daily INH (300 mg) in subjects at high risk for tuberculosis, rates of TB were comparable (7 of 3986 subjects in the combination-therapy group [cumulative rate, 0.19%] and in 15 of 3745 subjects in the INH-only group

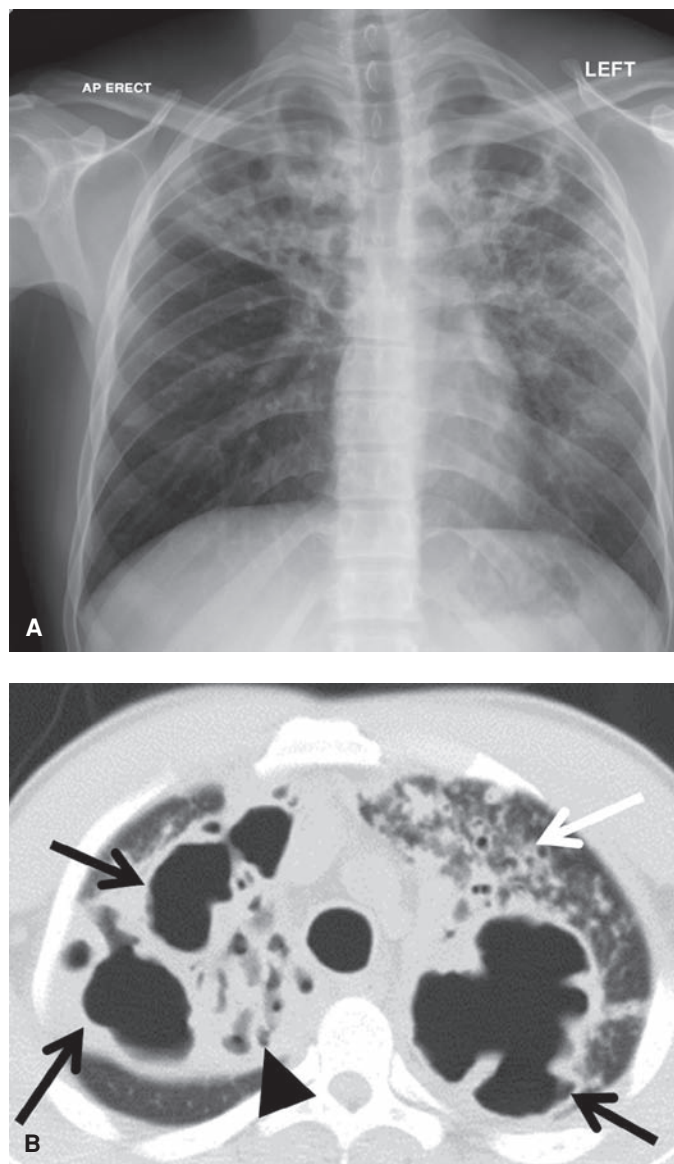

FIGURE 54-11 Reactivation tuberculosis with cavitary lesions in the upper lobes of a 35-year-old man. **A.** Frontal chest radiograph depicts large cavitary lesions in both upper lobes associated with bronchiectasis and fibronodular opacities. **B.** Noncontrast chest CT confirms the presence of irregular cavities in both upper lobes (black arrows), nodules (white arrow), and bronchiectasis (black arrowhead). (Courtesy of Carlos Santiago Restrepo, MD.)

[cumulative rate, 0.43%] and completion rates were higher.²² Three additional RCTs (Brazil, South Africa, and International) have shown that this combination regimen administered weekly for 12 weeks as directly observed therapy is as effective for preventing TB as other regimens and is more likely to be completed than the U.S. standard regimen of 9 months of INH daily without directly observed therapy.²¹

- Refusal of treatment for latent TB in another study at 32 clinics was 17.1% (95% CI, 14.5% to 20.0%) and 52.7% (95% CI, 48.5% to 56.8%) failed to complete the recommended course.²³

PREVENTION

- There is no currently available vaccine with adequate effectiveness for the prevention of TB,³ although approximately 10 vaccines are in the clinical trial phase.²⁴ Bacille Calmette-Guérin (BCG) vaccine, first released in 1921, can prevent up to 50% of TB cases.²⁵
- BCG vaccine also has a protective effect against meningitis and disseminated TB in children, although it does not appear to prevent primary infection or reactivation of latent pulmonary infection, the principal source of bacillary spread in many communities.
- In clinical trials in Guinea-Bissau, vaccination at birth of low-birthweight infants decreased mortality, while revaccination of children with BCG appeared to increase mortality, resulting in early discontinuation of the trial.^{26,27} The CDC recommends that BCG vaccine only be considered for very select persons who meet specific criteria and in consultation with a TB expert.²⁸
- In a RCT, the use of primary INH prophylaxis did not improve tuberculosis disease-free survival among HIV-infected children or tuberculosis infection-free survival among HIV-uninfected children immunized with BCG vaccine.²⁹
- CDC consensus-based recommendations to prevent TB spread include: not routinely hospitalizing patients with TB for diagnostic tests or care; separating patients with respiratory TB from immunocompromised patients; use of masks, gowns, or barrier nursing techniques if MDR TB is suspected or an aerosol-generating procedure is being performed; instructing patients with smear-positive pulmonary, laryngeal, or respiratory tract disease to avoid unnecessary contact with people from outside the household (e.g., avoid work, daycare facilities, or schools) for the first 2 weeks of treatment, and considering chemoprophylaxis for young children who are close contacts to avoid parental separation.³⁰

PROGNOSIS

- Without treatment, approximately one-third of individuals with active TB will die within 1 year and half within 5 years. Of those who survive 5 years, 60% will have undergone spontaneous remission and the remaining will continue to be infectious.³¹

FOLLOW-UP SOR

- Patients are considered contagious until they have been on adequate chemotherapy for a minimum of 2 weeks, have 3 negative

FIGURE 54-12 Histoplasmosis in a 33-year-old man with a 6-month history of fatigue. Chest x-ray shows a 4-cm mass overlying the right hilum and a lumpy contour of the left hilum that indicates lymphadenopathy. Histoplasmosis was diagnosed on bronchoscopy. (From Miller WT, Jr. *Diagnostic Thoracic Imaging*. New York, NY: McGraw-Hill; 2006:357, Figure 7-54 A.)

AFB sputum cultures (collected in 8- to 24-hour intervals with 1 early morning specimen), and show clinical improvement.³²

- Monitor clinical recovery, medication adverse effects and compliance with treatment monthly¹⁹; risk factors for noncompliance include lack of motivation, lack of perceived vulnerability, and poverty.
- Monitor response to treatment—Monthly sputum cultures should be obtained until culture negative (80% expected by 2 months). If culture positive at 3 or more months, consider drug resistance or treatment failure and institute additional evaluation and treatment. For those with extrapulmonary TB, monitor clinically.⁴
- CXR is not used for monitoring treatment as clearing lags behind clinical improvement. A CXR should be completed at the end of treatment for later comparison if reactivation is suspected.⁴
- Monitor drug toxicity⁴:
 - GI side effects and pruritus are common and can generally be managed without suspending treatment.
 - Hepatitis is the most common serious adverse event (symptoms include dark urine and decreased appetite); elevation of liver enzymes up to 3 times normal occurs in 20% and is of no clinical importance. Treatment (INH, pyrazinamide, or rifampin) should be discontinued for elevations of 5 times or more or with symptoms and drugs reintroduced one at a time after liver function has normalized.
 - Hypersensitivity reactions usually require discontinuing treatment.
 - Hyperuricemia and arthralgias may occur with pyrazinamide and can be managed with aspirin; the drug should be discontinued if the patient develops gouty arthritis.
 - Autoimmune thrombocytopenia may be caused by rifampin and requires discontinuing the drug.
 - Optic neuritis may occur with ethambutol and the drug should be discontinued. Visual acuity and color vision testing monthly if ethambutol is used for more than 2 months or in doses greater than 15 to 20 mg/kg.²⁹
- Routine measurements of hepatic and renal function and platelet count are not necessary during treatment unless patients have baseline abnormalities or are at increased risk of hepatotoxicity (e.g., hepatitis B or C virus infection, alcohol abuse).

PATIENT EDUCATION

- Identifying and testing household and other intimate contacts and maintaining follow-up are extremely important for preventing spread, insuring cure, and monitoring for drug toxicity (as below). The potential severity of TB should be emphasized.
- If available, patients should consider receiving treatment through a (directly observed therapy) short course program composed of 5 distinct elements: political commitment; microscopy services; drug supplies; surveillance and monitoring systems and use of highly efficacious regimens; and direct observation of treatment.³³ Although data are conflicting about the benefits of such programs, they may be better equipped to provide the intense services needed, especially in resource poor communities. Directly observed therapy is recommended for the 3-month combination rifampin and INH treatment.

- TB is not spread through direct contact, sharing food, or kissing. The best prevention of progression and spread is to take the prescribed medications regularly for the recommended duration and to avoid unnecessary contact with people from outside the household (e.g., avoid work, daycare facilities, or schools) for the first 2 weeks of treatment and until you have 3 negative AFB sputum cultures and feel better.

55 ASTHMA

Mindy A. Smith, MD, MS

PATIENT STORY

A 32-year-old Hispanic woman presents to your office with a chronic cough for 3 months. She states the cough is dry and started with a cold 3 months ago. She denies fever, chills, and night sweats. She has never been diagnosed with asthma or lung disease in the past. She does admit to having had persistent dry coughs that linger on after getting colds in the past. She is not sure what wheezing is but she has noticed a tight feeling in her chest at night with some whistling sound. On physical examination, her lungs are clear and she is moving air well. She is 5 feet tall and weighs 220 pounds, giving her a body mass index (BMI) of 43. Her peak expiratory flow (PEF) in the office is at 80% of predicted. Even though she is not wheezing her history and physical exam are highly suspicious for asthma. You prescribe a short-acting β_2 -agonist rescue inhaler with spacer and order pulmonary function tests (PFTs). You have your nurse provide asthma education (including proper use of an inhaler) and suggestions for weight loss.

The patient returns 1 week later and the cough is much improved. You review her PFTs (**Figure 55-1**) and note that she has reversible bronchospasm especially in the small airways (FEF_{25%-75%} shows a 70% improvement with inhaled albuterol). **Table 55-1** lists the meaning of typical abbreviations used with PFTs. Her lung volumes (**Figure 55-1B**) show hyperinflation with a high residual volume and her diffusing capacity is normal. The whole picture is consistent with asthma. An asthma action plan is created and a referral to a nutritionist is offered to help the patient with her obesity.

INTRODUCTION

Asthma is a chronic inflammatory airway disorder with variable airflow obstruction and bronchial hyperresponsiveness that is at least partially reversible, spontaneously or with treatment (e.g., β_2 -agonist treatment). Patients with asthma have recurrent episodes of wheezing, breathlessness, chest tightness, and cough (particularly at night or in the early morning).

EPIDEMIOLOGY

- Estimated prevalence of asthma in noninstitutionalized adults older than age 18 years in the United States (2010) is approximately 8.2% (18.7 million cases).¹ There are 7 million children (9.4%) who currently have asthma. Rates of asthma are increasing; the greatest rise in rates is among black children, an almost 50% increase between 2001 and 2009.²
- The number of deaths from asthma in 2009 was 3388 (1.1/100,000 population).¹
- Asthma accounts for 17 million visits per year (physician offices, emergency departments, and hospital outpatient sites).¹

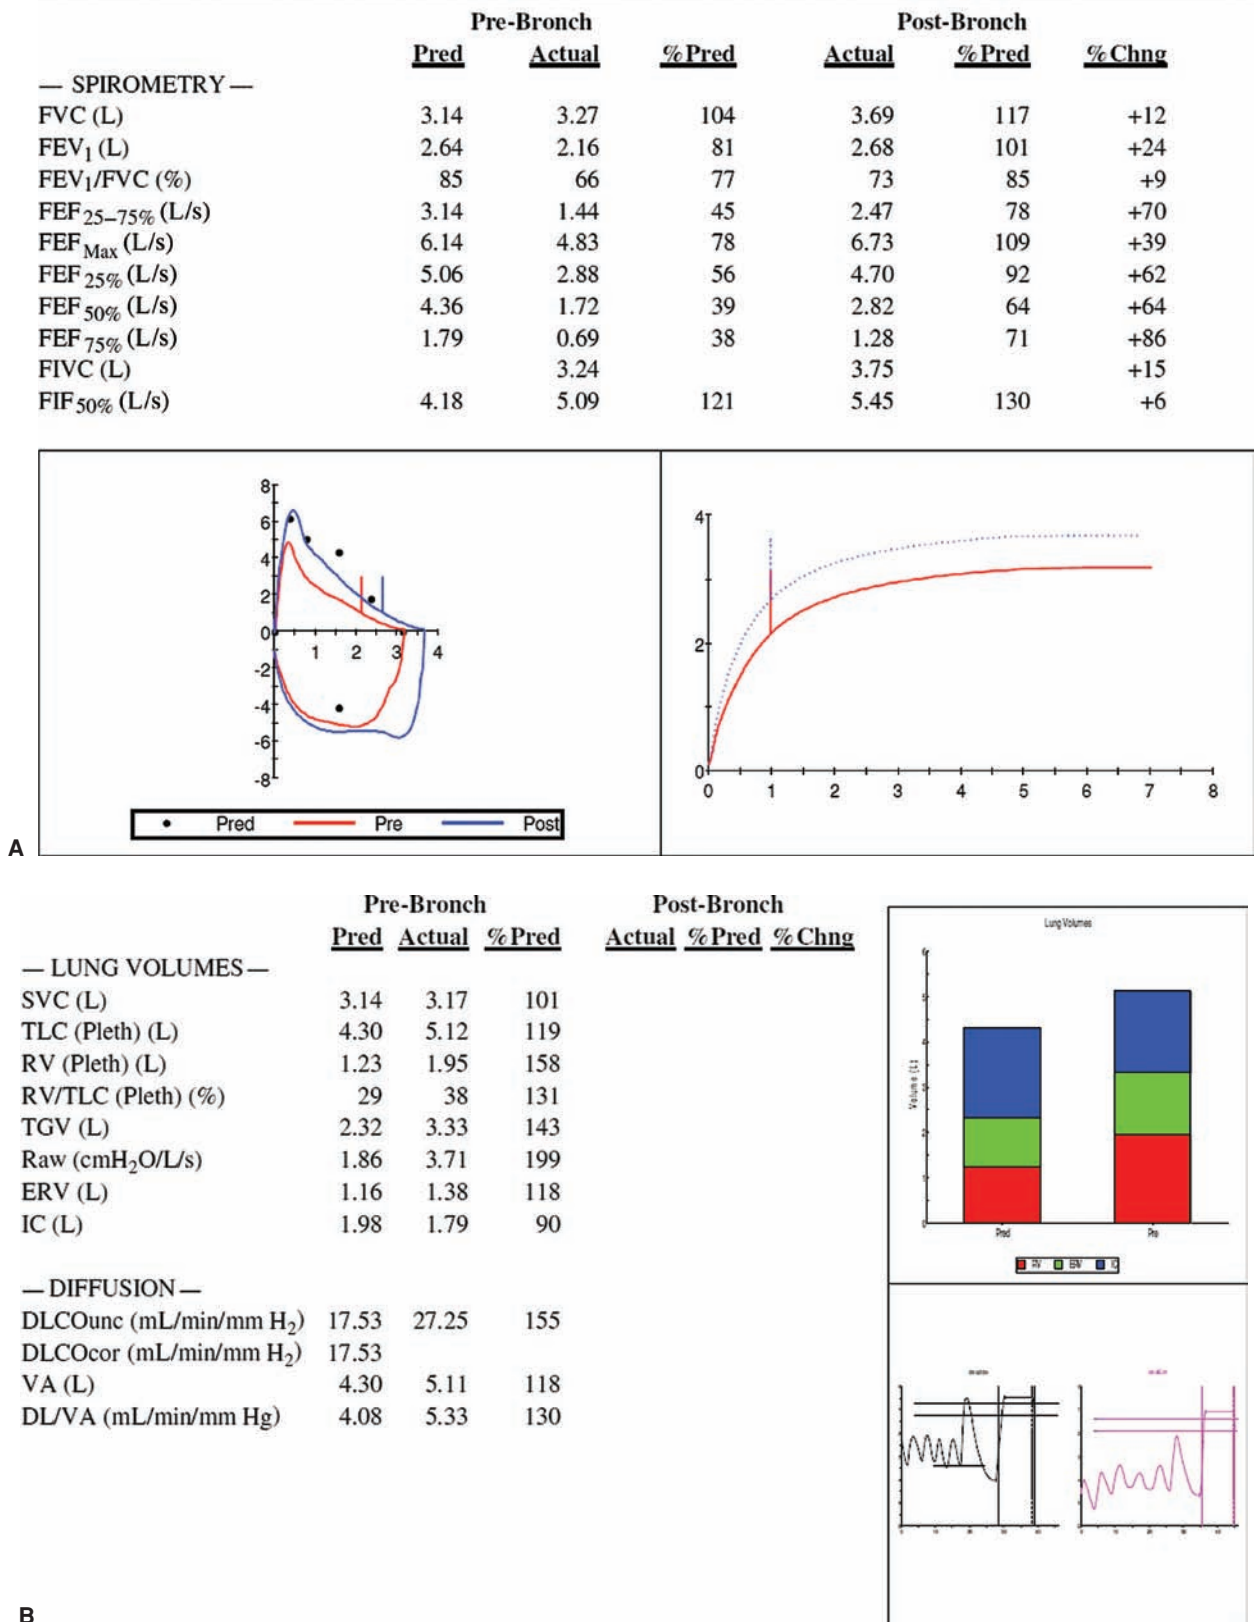

FIGURE 55-1 Pulmonary function tests in a woman with suspected asthma. **A.** Spirometry before and after bronchodilation with flow volumes loops and graph of forced vital capacity. The FEV₁ is normal, but the FEV₁/FVC ratio and FEF_{25-75%} are reduced. Following administration of bronchodilators, there is a good response especially in the small airways as represented by FEF_{25-75%}. **B.** Lung volumes are all increased (especially the residual volume), indicating overinflation and air trapping. The diffusing capacity is normal. Conclusions: Minimal airway obstruction, overinflation, and a response to bronchodilators are consistent with a diagnosis of asthma. The patient has minimal obstructive airways disease of the asthmatic type. %Chng, Percent change; %Pred, percent predicted; Pre-Bronch, prebronchodilation; Pred, predicted; Post-Bronch, postbronchodilation. See Table 55-1 for additional abbreviation explanations. (Courtesy of Richard P. Usatine, MD.)

TABLE 55-1 Pulmonary Function Tests: Key to Abbreviations

DLCO	Diffusing capacity of lung (using carbon monoxide measuring)
DL/VA	Diffusing capacity divided by alveolar volume
ERV (L)	Expiratory reserve volume
FEF _{25%} (L/s)	Forced expiratory flow rate when 25% of the FVC has been exhaled (slope of FVC curve at 25% exhaled)
FEF _{25–75%} (L/s)	Forced expiratory flow between 25% and 75% of capacity—same as maximal mid expiratory flow (MMFR)
FEF _{50%} (L/s)	Forced expiratory flow rate when 50% of the FVC has been exhaled
FEF _{75%} (L/s)	Forced expiratory flow rate when 75% of the FVC has been exhaled
FEF _{max} (L/s)	Forced expiratory flow maximum
FEV ₁ (L)	Forced vital capacity at 1 second
FEV ₁ /FVC %	FEV ₁ divided by FVC
FIF _{50%} (L/s)	Forced inspiratory flow at 50% capacity
FITC (L)	Forced inspiratory vital capacity
FVC (L)	Forced vital capacity
IC (L)	Inspiratory capacity
Raw	Airway resistance
RV (L)	Residual volume
RV/TLC	Residual volume divided by total lung capacity
SVC (L)	Slow vital capacity
TGV (L)	Thoracic gas volume
TLC (L)	Total lung capacity
VA (L)	Alveolar volume

- Asthma was the first-listed diagnosis for 479,000 hospital discharges in 2009 with an average length of stay of 4.3 days.¹
- Estimated direct costs associated with asthma in the United States grew from approximately \$53 billion in 2002 to approximately \$56 billion in 2007 (6% increase).²

ETIOLOGY AND PATHOPHYSIOLOGY

- Although the precise cause is unknown, early exposure to airborne allergens (e.g., house-dust mite, cockroach antigens) and childhood respiratory infections (e.g., respiratory syncytial virus, parainfluenza) are associated with asthma development.
- In addition to environmental factors, asthma has an inherited component, although the genetics involved remain complex.³ The gene ADAM33 (A Disintegrin And Metalloproteinase) may increase risk of asthma as metalloproteinases appear to affect airway remodeling.⁴ A recent nested case-control study found that genetic variation in the ATPAF1 gene predisposed children of different racial backgrounds to asthma.⁵

- The pulmonary obstruction characterizing asthma results from combinations of mucosal swelling, mucous production, constriction of bronchiolar smooth muscles and neutrophils (the latter, particularly important in smokers or those with occupational asthma).⁴ The smaller airways of children make them particularly susceptible. Over time, airway smooth muscle hypertrophy and hyperplasia, remodeling (thickening of the subbasement membrane, subepithelial fibrosis, and vascular proliferation and dilation), along with mucous plugging complicate the disease.⁴
- Allergen-induced acute bronchospasm involves immunoglobulin-E (IgE)-dependent release of mast cell mediators.⁴

RISK FACTORS

Based on a cohort study, early life (first 5 years) risk factors for diagnosed asthma at age 10 years includes:⁶

- Family history of asthma (maternal [odds ratio (OR), 2.26; 95% confidence interval (CI), 1.24 to 3.73]; paternal [OR, 2.30; 95% CI, 1.17 to 4.52]; sibling [OR, 2.00; 95% CI, 1.16 to 3.43]).
- Recurrent chest infections at 1 year of age (OR, 2.67; 95% CI, 1.12 to 6.40) and 2 years of age (OR, 4.11; 95% CI, 2.06 to 8.18).
- Atopy at 4 years of age (OR, 7.22; 95% CI, 4.13 to 12.62).
- Parental smoking at 1 year of age (OR, 1.99; 95% CI, 1.15 to 3.45).
- Male gender (OR, 1.72; 95% CI, 1.01 to 2.95).
- Recent use of acetaminophen has also been associated with asthma symptoms in adolescents (OR, 1.43; 95% CI, 1.33 to 1.53 and OR, 2.51; 95% CI, 2.33 to 2.70 for at least once a year and at least once a month use vs. no use, respectively).⁷ One possible mechanism is through acetaminophen reducing the immune response and prolonging rhinovirus infection.⁸
- Modifiable risk factors include obesity (OR 3.3 for adult-onset asthma) and tobacco smoking; the latter also increases the risk of occupational asthma.⁴ In one study, consumption of salty snacks (OR 4.8; 95% CI, 1.50 to 15.8) was strongly associated with the presence of asthma symptoms, especially in children with television/video-game viewing of more than 2 hours per day.⁹

DIAGNOSIS

The diagnosis of asthma is made on clinical suspicion (presence of symptoms of recurrent and partially reversible airflow obstruction and airway hyperresponsiveness) and confirmed with spirometry.³ Alternative diagnoses should be excluded.

CLINICAL FEATURES

Asthma's most common symptoms are recurrent wheezing, difficulty breathing, chest tightness, and cough. An absence of wheezing or normal physical exam does not exclude asthma.³ In fact, up to 25% of patients with asthma have normal physical exams even though abnormalities are seen on pulmonary function testing.⁴ As part of the diagnosis of asthma, ask about the following:³

- Pattern of symptoms and precipitating factors. Symptoms often occur or worsen at night and during exercise, viral infection, exposure to inhalant allergens or irritants (e.g., tobacco smoke, wood smoke, airborne chemicals), changes in weather, strong emotional expression (laughing hard or crying), menstrual cycle, and stress.³
- Family history of asthma, allergy, or atopy in close relatives.
- Social history (e.g., daycare, workplace, social support).
- History of exacerbations (e.g., frequency, duration, treatment) and impact on patient and family.

Findings on physical exam may include:³

- Upper respiratory tract—Increased nasal secretion, mucosal swelling, and/or nasal polyp.
- Lungs—Decreased intensity of breath sounds is the most common (33% to 65% of patients).⁴ Additional findings may include wheezing, prolonged phase of forced exhalation, use of accessory respiratory muscles, appearance of hunched shoulders, and chest deformity. During a severe exacerbation of asthma, minimal airflow may result in no audible wheezing.
- Skin—Atopic dermatitis and/or eczema (Chapters 145, Atopic Dermatitis, 147, Hand Eczema, and 148, Nummular Eczema). There is a strong association between asthma, allergic rhinoconjunctivitis, and eczema (**Figure 55-2**), although the “atopic or allergic triad,” with the coexistence of all three conditions at one time (**Figure 55-3**), is not very common. Children with asthma are also more likely to develop pityriasis alba, a chronic skin disorder characterized by patches of lighter skin mainly on the face (**Figure 55-4**). In a U.S. study of children with physician-confirmed atopic dermatitis (N = 2270), 38% reported symptoms of asthma and allergic rhinitis on a survey¹⁰; similarly in a population study in Taiwan using the National Insurance register, of the 66,446 individuals diagnosed with atopic dermatitis, approximately 50% had a concomitant diagnosis of allergic rhinitis and/or asthma.¹¹ Data support a sequence of atopic manifestations beginning typically with atopic dermatitis in infancy followed by allergic rhinitis and/or asthma in later stages.¹²

Findings in patients with status asthmaticus (prolonged/severe asthma attack that is not responsive to standard treatment) may include:⁴

- Tachycardia (heart rate >120 beats/min) and tachypnea (respiratory rate >30 breaths/min).
- Use of accessory respiratory muscles.
- Pulsus paradoxus (inspiratory decrease in systolic blood pressure >10 mm Hg).
- Mental status changes (as a consequence of hypoxia and hypercapnia).
- Paradoxical abdominal and diaphragmatic movement on inspiration.

LABORATORY TESTING

Spirometry is recommended by National Asthma Education Program (NAEP) for all patients older than 4 years of age to determine airway obstruction that is at least partially reversible (**Figures 55-1, 55-5, and 55-6**).³ **SOR B**

FIGURE 55-2 Patient with severe asthma, atopic dermatitis, and allergic rhinitis—atopic triad. (Courtesy of Richard P. Usatine, MD.)

FIGURE 55-3 Two-year-old child with the “atopic triad” showing skin manifestations of atopic dermatitis. (Courtesy of Richard P. Usatine, MD.)

- Assess severity—Severity is defined as the intrinsic intensity of the disease process.³ The NAEP divides severity into four groups: intermittent, persistent-mild, persistent-moderate, and persistent-severe (**Table 55-2**).
- Initially, severity can be assessed in the office, urgent, or emergency care setting with predicted forced expiratory volume in 1 second (FEV₁) or PEF; a value of less than 40% indicates a severe exacerbation. A value of equal to or greater than 70% predicted FEV₁ or PEF is a goal for discharge from the emergency care setting.
- Once asthma control is achieved, severity can be assessed by the step of care required for control (i.e., amount of medication) (**Table 55-2**).

Additional tests that may be useful include:³

- Pulmonary function testing if a diagnosis of chronic obstructive pulmonary disease (COPD), restrictive lung disease, or vocal cord dysfunction is considered.
- Bronchoprovocation (using methacholine, histamine, cold air, or exercise challenge) if spirometry is normal or near-normal and asthma is still suspected; a negative test is helpful in ruling out asthma.
- Pulse oximetry or arterial blood gas if hypoxia is suspected (e.g., cyanosis, rapid respiratory rate).
- In the emergency room setting, B-type natriuretic peptide can help distinguish between heart failure and pulmonary disease.⁴

FIGURE 55-4 Ten-year-old girl with pityriasis alba, atopic dermatitis, and asthma under control. (Courtesy of Richard P. Usatine, MD.)

IMAGING

A chest X-ray (CXR) is not useful for diagnosis but is helpful for excluding other diseases (e.g., pneumonia) or identifying comorbidity (e.g., heart failure). The main finding on CXR is hyperinflation (occurring in approximately 45% of patients with asthma).⁴ Hyperinflation is manifested by the following:

- Increased anteroposterior (AP) diameter.
- Increased retrosternal air space (**Figure 55-7**).
- Infracardiac air.
- Low-set flattened diaphragms (best assessed in lateral chest).
- Vertical heart.

FIGURE 55-5 Graph of lung volumes showing the relationship of tidal volume to vital capacity and other important lung volumes. (Courtesy of Wikimedia Commons and Vihsadas at <http://commons.wikimedia.org/wiki/File:LungVolume.jpg>)

Atelectasis is another finding seen during acute severe episodes (Figure 55-8).

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of an infant or child with wheezing includes:³

- Upper airway disease (e.g., allergic rhinitis, sinusitis)—Exam or imaging helps differentiate.
- Airway obstruction (foreign body, vascular rings, vocal cord dysfunction, tracheal stenosis, enlarged lymph node or tumor, infection, cystic fibrosis, heart disease)—Imaging helps differentiate.
- Other causes, such as recurrent cough or reflux. Cough-variant asthma (only cough) occurs especially in young children.

The differential diagnosis of an adult with episodic wheezing, chest-tightness, cough, and difficulty breathing includes:

- COPD—Usually begins after age 40 years with dyspnea (persistent or progressive or worse with exercise), chronic cough (even if intermittent or nonproductive) and/or sputum production, and/or a history of COPD risk factors, including a family history of COPD (Chapter 56, Chronic Obstructive Pulmonary Disease).
- Chronic bronchitis—A clinical diagnosis defined as the presence of cough and sputum production of at least 3 months in two consecutive years¹³; although often seen in patients with COPD, chronic bronchitis can occur in patients with normal spirometry.
- Pneumonia—Symptoms include fever, chills, and pleuritic chest pain; physical findings include dullness to percussion, bronchial breathing, egophony (E to A change), and crackles with area of infiltrate/pneumonia usually confirmed on CXR (Chapter 53, Pneumonia).
- Tuberculosis—Any age; symptoms of chronic cough. CXR shows infiltrate; positive culture confirms (Chapter 54, Tuberculosis).

FIGURE 55-6 Patient having pulmonary function tests (Courtesy of Richard P. Usatine, MD.)

TABLE 55-2 Classification of Asthma Severity

	Intermittent	Mild Persistent	Moderate Persistent	Severe Persistent
Symptoms	≤2 times/week	More than 2 days per week	Daily	Throughout the day
Nighttime Awakenings	≤2 times/month	3–4 x per month	Greater than once per week but not nightly	Nightly
Inhaler Use for symptom control (rescue use)	≤2 days/week	> 2 days per week, but not daily	Daily	Several times per day
Interference with Normal Activity	None	Minor limitation	Some limitation	Extremely limited
Lung Function	FEV ₁ >80% predicted and normal between exacerbations	FEV ₁ >80% predicted	FEV ₁ >60%–80% predicted	FEV ₁ less than 60% predicted

Source: National Asthma Education and Prevention Program. *Guidelines for the Diagnosis and Management of Asthma*—<http://www.nhlbi.nih.gov/guidelines/asthma/asthsumm.pdf>.

FIGURE 55-7 Acute asthma exacerbation with increased lung volumes on chest X-ray. The lateral projection reveals enlargement of the retrosternal clear space (arrow). (Courtesy of Carlos Santiago Restrepo, MD.)

- Congestive heart failure—Nonspecific basilar crackles, CXR shows cardiomegaly, echocardiogram confirms (Chapter 48, Heart Failure).
- Cough secondary to drugs (e.g., angiotensin-converting enzyme inhibitor), vocal cord dysfunction—Identified on medication history or PFT.
- Asthma may occur in conjunction with these conditions.

MANAGEMENT

NAEP outlines four components of care: assessment and monitoring, provision of education, control of environmental factors and comorbid conditions, and use of medications.³ The goals of asthma therapy are two-fold:³

- Reduce impairment—Prevent chronic symptoms, require infrequent (twice weekly or less) use of rescue inhaler, maintain near normal pulmonary function, maintain normal activity levels, meet patient and family expectations and satisfaction with care.
- Reduce risk—Prevent recurrent exacerbations and minimize need for emergency or hospital care, prevent loss of lung function (for children, prevent reduced lung growth), and provide optimal pharmacotherapy while minimizing side effects and adverse effects.

NONPHARMACOLOGIC

- Exercise should be encouraged. In a randomized clinical trial (RCT) of aerobic exercise in patients with persistent asthma, the group randomized to exercise showed significant improvements in physical limitations, frequency of symptoms, health-related quality

FIGURE 55-8 Acute asthma exacerbation in a 28-year-old man. Frontal chest radiograph demonstrates increased lung volumes and ill-defined opacity in the right infrahilar region consistent with middle lobe segmental atelectasis (arrow). (Courtesy of Carlos Santiago Restrepo, MD.)

of life, number of asthma-symptom-free days, and anxiety and depression levels over the control group (education and breathing exercises only).¹⁴

- For patients exposed to secondhand smoke in the home, use of high-efficiency particulate-arresting (HEPA) air cleaners was shown in one RCT to decrease unscheduled asthma visits for children ages 6 to 12 years; there was no difference between groups in parent-reported symptoms.¹⁵
- Dietary changes may also be useful. In a cross-sectional study, greater adherence to a Mediterranean-type diet was associated with a lower prevalence of asthma symptoms.¹⁶
- Provide patient education. **SOR A** Pediatric asthma education was shown in a metaanalysis to reduce mean number of hospitalizations and emergency department (ED) visits and the odds of an ED visit for asthma¹⁷; there was no influence of education on the odds of hospitalization or mean number of urgent physician visits. Reduction in hospital and ED visits and missed work/school also has been shown for self-management education with written asthma action plans and physician review.⁴ In one RCT, peer-led asthma education compared to adult-led education was associated with more positive attitudes at 6 months and higher quality of life at 6 and 9 months.¹⁸
- Consider interventions to control home environmental triggers; comprehensive individual programs may reduce symptom days.⁴ **SOR B**
 - Many people who have asthma are allergic to dust mites (**Figure 55-9**). Two relatively easy interventions to decrease dust mite exposure are to encase pillows and mattresses in special dust-mite-proof covers and wash the sheets and blankets on the bed each week in hot water.³
 - Other suggestions for reducing environmental triggers can be found in the NAEP reference³ at <http://www.nhlbi.nih.gov/guidelines/asthma/asthsumm.pdf>.

FIGURE 55-9 Dust mites under the microscope. Dust mites are a common allergen for patients who suffer from asthma and allergic rhinitis. Environmental control to minimize dust mite exposure can help control asthma for some individuals. (Courtesy of Richard P. Usatine, MD.)

MEDICATIONS

To determine appropriate medication management, assess severity based on symptoms, medication usage, and lung function (**Figure 55-1**). In addition, assess risk based on number of exacerbations requiring systemic steroids (**Figure 55-1**). For children, severity is assessed through symptoms, night time awakenings, interference with normal activity, and lung function; the latter if the child is older than 4 years of age. Risk is assessed by exacerbations requiring systemic steroids and treatment-related adverse effects.³ A chart for children is available in the NAEP reference to facilitate these assessments and includes treatment protocols.³

For youths age 12 years and up and adults, persistent asthma can then be divided into mild, moderate, or severe; these categories are matched to steps of medications described below and shown in **Figure 55-1**. Children are categorized as controlled, not-well controlled, or very poorly controlled with steps of care suggested as well. The NAEP six steps of care with respect to asthma medications are:³

- **Step 1:** For all patients of all ages with intermittent asthma, an inhaled short-acting β_2 -agonist (SABA) is recommended. **SOR A** Metered-dose inhalers with spacers are at least as effective (with fewer side effects) as nebulized treatment for most patients.

- **Step 2:** Low-dose inhaled corticosteroids (ICSs) are the preferred long-term control therapy for all ages with persistent asthma. **SOR A** Alternatives include cromolyn inhaler, leukotriene receptor antagonist (LTRA), nedocromil, or theophylline.
 - LTRAs are less effective than ICSs but better than placebo.³ **SOR A**
 - In a RCT of preschool-age children with recurrent wheezing (N = 278), intermittent budesonide inhalation suspension (1 mg twice daily for 7 days, starting early during a predefined respiratory tract illness) was as effective as a daily low-dose regimen (0.5 mg nightly) in preventing acute exacerbations (about 1 fewer per patient-year) while reducing mean exposure to budesonide.¹⁹
- **Step 3:** Combination low-dose ICSs and long-acting β_2 -agonist (LABA) or medium-dose ICSs are equally preferred options in patients older than 4 years of age.³ **SOR A** Alternatives include low-dose ICS plus LTRA (less effective than ICS and LABA), theophylline, or zileuton. Theophylline requires monitoring serum concentration levels. Zileuton is less desirable because of limited supporting data and the need to monitor liver function. Authors of a Cochrane review found the combination ICS-LABA modestly more effective in reducing the risk of exacerbations requiring oral corticosteroids than higher-dose ICSs for adolescents and adults, but a trend toward increased risks of exacerbation and hospitalization among children.²⁰
 - For patients age 4 years and younger, low-dose ICSs and LABA are suggested initially by NAEP, followed by increasing the ICS dose if persistent low lung function and more than 2 days per week of impairment³; the ICS-LABA combination may not reduce exacerbations but appears to improve PEF and growth.²¹ Although serious asthma-related events (asthma-related deaths, intubations, and hospitalizations) attributable to LABAs appear to be greatest among children, in a metaanalysis, there was no statistically significant difference in serious events by age group for the subgroup on both ICS and LABA.²²
 - One trial of step-up therapy for children with not-well-controlled persistent asthma on ICSs found that although combination ICS-LABA was most likely to result in a best response, some children had a best response to doubling ICSs or combination ICSs-LTRA.²³
- **Step 4:** Combination medium-dose ICS and LABA. Alternatives are combination medium-dose ICS plus LTRA, theophylline, or zileuton (see above).
- **Step 5:** Combination high-dose ICS and LABA.
- **Step 6:** Combination high-dose ICS and LABA plus oral corticosteroid.

Other drug options:

- In a RCT, the addition of tiotropium bromide (a long-acting anticholinergic agent approved for the treatment of COPD but not asthma) to inhaled ICSs was superior to doubling the ICS dose in improving lung function and symptoms and noninferior to the addition of a LABA to ICSs (step 3 above).²⁴
- Omalizumab should be considered for patients older than 11 years of age who have allergies or for adults who require step 5 or 6 care (severe asthma).³ In a RCT with inner-city children, adolescents, and young adults (N = 419) with persistent asthma, omalizumab reduced symptom days and the proportion of subjects who had 1 or more exacerbations (30.3% vs. 48.8% on placebo).²⁵

- To assist with smoking cessation, consider nicotine-replacement therapy (bupropion [150 mg, twice daily], varenicline [1 mg twice daily], nortriptyline [75 to 100 mg daily], or nicotine replacement [gum, inhaler, spray, patch]) and supportive counseling and follow-up; using these interventions improves rates of smoking cessation by up to two-fold (Chapter 236, Tobacco Addiction).^{26–28} **SOR A**
- In patients with persistent asthma attributed to allergies, consider allergy immunotherapy.³ **SOR B** One metaanalysis concluded that specific immunotherapy for patients with positive skin tests resulted in a reduction in need for increased medications (number needed to treat = 5) and another study in patients with high IgE found immunotherapy reduced exacerbations.⁴
- Using proton pump inhibitor therapy in adults with asthma is unlikely to add significant benefit.²⁹ Among children with uncontrolled asthma on ICSs but without GI reflux symptoms, the addition of a lansoprazole (versus placebo) resulted in no improvement in symptoms or lung function, but increased adverse events.³⁰

For patients with a mild *exacerbation* of asthma (dyspnea with activity, PEF \geq 70% predicted or personal best), SABAs, and sometimes oral corticosteroids, are used for home management of patients following their action plan. NAEP does not recommend doubling the dose of ICSs for home management versus oral steroids for exacerbations.³ A Cochrane review concluded that a short course of oral steroids was effective in reducing the number of relapses to additional care, hospitalizations, and use of SABA without an apparent increase in side effects.³¹

- Moderate exacerbation (dyspnea interferes with usual activity, PEF 40% to 69% predicted or personal best) usually requires an office or ED visit; SABA and oral corticosteroids (typically 40 to 60 mg prednisone for adults and 1 to 2 mg/kg per day of prednisolone liquid in two divided doses) are recommended for 3 to 10 days. **SOR A** SABA can be administered every 20 minutes as needed and the addition of inhaled ipratropium bromide may reduce the need for hospitalization (0.68 to 0.75).⁴ **SOR A** Symptoms usually abate in 1 to 2 days.
- Severe exacerbation (dyspnea at rest, PEF $<$ 40% predicted or personal best) usually requires an ED visit and hospitalization is likely; combination SABA-anticholinergic nebulized treatment hourly or continuously as needed, oral corticosteroids, adjunctive treatment as needed (see below). Symptoms last for longer than 3 days after treatment begins.
- Life-threatening exacerbation (too dyspneic to speak, diaphoresis, PEF $<$ 25% predicted or personal best) requires an ED visit and/or hospitalization; consider intensive care unit, SABA-anticholinergic, intravenous corticosteroids, and adjunctive therapies.
- Oxygen therapy—Use to correct hypoxia in patients with moderate to life-threatening exacerbations; maintain O₂ saturation above 90%.^{3,4} **SOR C**
- Consider intravenous magnesium sulfate or heliox-driven albuterol nebulization if severe exacerbation and unresponsive to treatment after initial assessments.
- Monitor response to treatment with serial assessments of FEV₁ or PEF. Pulse oximetry may be useful in children for assessing initial

severity—a result of less than 92% to 94% after 1 hour is an indication for hospitalization.³ For adults, pulse oximetry may be useful for severe episodes or when unable to perform lung function testing; repeat assessments for hypoxia are useful for predicting need for hospitalization, as are signs and symptoms at 1 hour posttreatment.

- Patients with severe or life-threatening exacerbation unresponsive to initial treatments may require intubation and mechanical ventilation. Drowsiness may be a symptom of impending respiratory failure.
- The following should not be used as they have no supporting evidence and may delay effective treatment: drinking large volumes of liquids; breathing warm, moist air; using nonprescription products, such as antihistamines or cold remedies; and pursed-lip and other forms of breathing.³ In addition, the NAEP does not recommend use of methylxanthines, antibiotics (except as needed for comorbid conditions), aggressive hydration, chest physical therapy, mucolytics, or sedation in the ED or hospital setting.³

REFERRAL

- Consider referral to an asthma specialist if signs and symptoms are atypical, there are problems in assessing other diagnoses, or if additional specialized testing is needed.
- Referral or consultation should also be considered if there are difficulties achieving or maintaining control of asthma, if the patient required more than two bursts of oral systemic corticosteroids in 1 year or has an exacerbation requiring hospitalization, or if immunotherapy or omalizumab is considered.³
- Consultation with an asthma specialist should be conducted for patients with persistent asthma requiring step 4 care or higher and considered if a patient requires step 3 care.³

PREVENTION AND SCREENING

- Smoking cessation and avoidance of secondhand smoke, limiting occupational exposures and exposure to indoor air pollution may be preventive.
- Influenza and pneumococcal vaccination are recommended.³ **SOR B**
- Despite limited data, vitamins A, D, and E; zinc; fruits and vegetables; and a Mediterranean diet may be useful for the prevention of asthma.³² In addition, raw cow's milk consumption appears protective (adjusted OR, 0.59; 95% CI, 0.46 to 0.74).³³

PROGNOSIS

- More than half of children with asthma will no longer have symptoms by age 6 years.⁴
- In a metaanalysis, maternal asthma was associated with an increased risk of low birthweight (relative risk [RR], 1.46; 95% CI 1.22 to 1.75), small for gestational age (RR, 1.22; 95% CI 1.14 to 1.31), preterm delivery (RR, 1.41; 95% CI 1.22 to 1.61), and preeclampsia (RR, 1.54; 95% CI 1.32 to 1.81).³⁴ The RR of preterm delivery and preterm labor became nonsignificant by active asthma management. Pregnancy does not appear to increase asthma severity, provided women continue to use their prescribed medications.³⁵

- Among children, factors predictive of an asthma exacerbation include bronchiolitis or pneumonia during infancy, maternal eczema, paternal history of hay fever, asthma symptoms lasting 3 or more months/year, more than four scheduled physician visits for asthma in the previous year, and use of certain medications (SABAs, antiinflammatory medications, and one or more courses of oral steroids) in the prior year.³⁶ A 17-item checklist assessing asthma symptoms, use of medications and health-care services, and history has been demonstrated to be helpful for identifying children at high- or low-risk for asthma exacerbations.³⁶
- For patients with an asthma exacerbation, the following factors place a patient at higher risk of asthma-related death; these patients should be advised to seek medical care early during an exacerbation:³
 - Previous severe exacerbation (e.g., intubation or intensive care unit admission for asthma).
 - Two or more hospitalizations or more than three ED visits in the past year.
 - Use of more than two canisters of SABA per month.
 - Difficulty perceiving airway obstruction or the severity of worsening asthma.
 - Low socioeconomic status or inner-city resident.

FOLLOW-UP

Many patients have asthma that is not well-controlled. In a cross-sectional study of 29 pediatric practices (n = 2429), 46% reported uncontrolled asthma (defined as a Childhood Asthma Control Test [C-ACT] or the Asthma Control Test [ACT] less than or equal to 19).³⁷

One of the new aspects of the NAEP 2007 guideline is the focus on monitoring asthma severity and control, the latter defined as the degree to which manifestations of asthma are minimized by therapeutic interventions and the therapy goals are met.

- At each visit ask about frequency and intensity of symptoms and functional limitations currently or recently experienced (impairment). A self-assessment sheet for follow-up visits is available in the NAEP document and a simple symptom checklist can be downloaded from <http://www.qvar.com/asthma/asthma-symptoms-checklist.aspx> (accessed February 2012). Severity can be measured by the step of care required to maintain control (**Figure 55-1**).³ **SOR** **C**
- In addition, at each visit, assess the likelihood of either asthma exacerbations, progressive decline in lung function (or lung growth for children), or risk of medication adverse effects. A patient self-assessment sheet rating asthma control (e.g., symptoms, PEF) and medication use is available in the NAEP reference.³ Provision of a visually standardized, interpreted peak-flow graph to assist in understanding when to add medication or contact a healthcare provider may reduce need for oral steroids and urgent care visits.³⁸
- For patients on medications, monitor treatment effectiveness (“Have you noticed a difference, for example, less breathlessness?”) and side effects. Observe inhaler technique at least once to ensure optimal delivery.
- For smokers, encourage cessation.
- Document exacerbations/hospitalizations—This may indicate a need for additional treatment.

- Monitor for comorbidities (e.g., heart disease, chronic lung disease) and maximize control of those conditions.
- Measurement of fractional nitric oxide (NO) concentration in exhaled breath (Fe[NO]) is a quantitative, noninvasive method of measuring airway inflammation.³⁹ It is under investigation as a complementary tool to other ways of assessing airways disease, including asthma.

PATIENT EDUCATION

- Smoking cessation should be strongly and repeatedly encouraged. Exercise should also be encouraged along with weight loss, if obese, or maintenance of a healthy weight.
- The NAEP suggests that key educational messages include basic facts about asthma, the role of medications (i.e., rescue/short-term vs. control/long-term), and patient skills (e.g., correct inhaler technique, self-monitoring).
- Creation of an asthma action plan can be helpful in promoting self-management and greater understanding of warning signs of worsening asthma. An example of an action plan can be found in the NAEP document.³ Asthma action plans usually use three zones, similar to traffic lights, with green zone representing good control (i.e., few symptoms, PEF 80% to 100%), yellow zone representing worsening or not-well-controlled asthma (i.e., mild to moderate symptoms, PEF 50% to 80%), and red zone representing an alert or warning (i.e., severe symptoms, PEF <50%), with advice to seek emergency care if not better after 15 minutes of rescue medication use and unable to reach their health-care provider. Each zone contains instructions for management that the primary care provider can modify.

56 CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Mindy A. Smith, MD, MS

PATIENT STORY

A 74-year-old woman and longtime smoker presents with fatigue and shortness of breath. She has not seen a physician for many years and says she has been basically healthy. On physical examination, she is found to be pale, mildly cachectic, and her lips are cyanotic. Her breath sounds are distant, although crackles can be heard in both lung bases. Her heart sounds are best heard in the epigastrium; a third heart sound is present. She has mild peripheral edema. Her resting pulse oximetry is 74%. Her chest X-ray (CXR) shows emphysema (**Figure 56-1**) and her echocardiogram confirms heart failure.

INTRODUCTION

Chronic obstructive pulmonary disease (COPD) is defined as a disease state characterized by airflow limitation that is usually progressive and associated with an abnormal inflammatory response of the lung to noxious particles or gases.¹ COPD is preventable and treatable. Some patients have significant extrapulmonary effects (particularly cardiac) that may contribute to disease severity. Worldwide, tobacco smoke is the primary cause of COPD (**Figure 56-2**).

SYNONYMS

Emphysema (technically refers to destruction of the alveoli).

EPIDEMIOLOGY

- Estimated prevalence of COPD in adults older than age 18 years in the United States (2008) is about 13.2 million cases, or 4% of the population (95% confidence interval [CI], 3.8 to 4.1).²
- Fourth leading cause of death both in United States and worldwide. Mortality rates have declined for men from 1999 to 2006 (57 per 100,000 to 46.4 per 100,000) and remained fairly stable for women (35.3 per 100,000 to 34.2 per 100,000).³
- In a study in Latin America, prevalence rates ranged from 7.8% to 19.7% of the population;⁴ a prevalence of between 3% and 11% has been reported in never-smokers.¹ This high rate among never-smokers is most likely related to indoor cooking with open wood fires.
- In a Swedish study of COPD (birth cohorts from 1919 to 1950), the 10-year cumulative incidence rate of COPD was 13.5% using Global Initiative for Chronic Obstructive Lung Disease (GOLD) criteria (**Table 56-1**) based on 1109 patients with baseline

FIGURE 56-1 Emphysema with mild hyperinflation and increased interstitial markings. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill; 2006:106, Figure 3-37 A. Copyright 2006.)

FIGURE 56-2 Gross pathology of lung showing centrilobular emphysema caused by tobacco smoking. Close-up of cut surface shows multiple cavities lined by heavy black carbon deposits. (Courtesy of Centers for Disease Control and Prevention [CDC] and Dr. Edwin P. Ewing, Jr.)

TABLE 56-1 COPD Severity—GOLD Grade

Grade	FEV ₁ /FVC	FEV ₁
Mild COPD (GOLD 1)	<0.7	≥80% predicted
Moderate COPD (GOLD 2)	<0.7	<80% but ≥50% predicted
Severe COPD (GOLD 3)	<0.7	<50% but ≥30% predicted
Very severe COPD (GOLD 4)	<0.7	<30% predicted or FEV ₁ <50% with respiratory failure or right-sided heart failure

Abbreviations: FEV₁, forced expiratory volume in 1 second; FVC, forced vital capacity.

respiratory symptoms (76.6% of the original symptomatic cohort and 16.7% of the total cohort).⁵

- Estimated direct costs associated with COPD in the United States are more than \$29 billion with additional indirect costs of \$20.4 billion.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- Mediated by chronic inflammatory responses to environmental factors, especially cigarette smoke, that results in recruitment of inflammatory cells in terminal airspaces and release of elastolytic proteinases that damage the extracellular lung matrix and cause ineffective repair of elastin and other matrix components.
- Oxidative stress may be an important amplifying mechanism in COPD development and exacerbations.¹ In addition, there appears to be an imbalance between proteases and antiproteases in the lungs of patients with COPD.
- The inflammatory process leads to obstruction and later fibrosis of small airways and the destruction of lung parenchyma. Circulating inflammatory mediators may contribute to muscle wasting and cachexia and worsen comorbidities such as heart failure and diabetes.¹
- Gas exchange abnormalities result in hypoxemia and hypercapnia.
- Pulmonary hypertension may occur as a result of hypoxic vasoconstriction of small pulmonary arteries.
- Genetic mutations (e.g., α_1 -antitrypsin deficiency [1% to 2% of cases; affects 1 in 2000 to 5000 individuals]) are present in some patients. Suspect a genetic mutation when emphysema is found in a patient age 45 to 50 years or younger, a positive family history of COPD, primarily basilar disease, or a minimal smoking history.⁶ Single-nucleotide polymorphisms at three loci—TNS1, GSTCD, and HTR4—are associated with COPD, as is genetic variation in the transcription factor SOX5.^{7,8}

RISK FACTORS

- Smoking (direct and passive)—COPD relative risk (RR) for ever smoking is 2.89 (95% CI, 2.63 to 3.17) and RR for current smoking is 3.51 (95% CI, 3.08 to 3.99).⁹

- Airway hypersensitivity (15% of the population attributable risk).¹
- Occupational exposures (e.g., gold and coal mining, cotton textile dust).^{1,2,6} The estimated fraction of COPD symptoms or functional impairment attributed to these exposures is 10% to 20%.¹
- Indoor air pollution from burning wood and other biomass fuels, particularly with open fires, poorly functioning stoves, and poorly ventilated dwellings.¹
- Reduced maximal attained lung function (e.g., preterm vs. full-term infants).¹
- Infections (e.g., early childhood infection, chronic bronchitis, HIV, tuberculosis).¹
- Poverty.
- Parental history of COPD (odds ratio [OR] 1.73).¹⁰
- α_1 -antitrypsin deficiency (genetic disorder).

DIAGNOSIS

A diagnosis of COPD should be considered in a patient older than age 40 years with dyspnea (persistent or progressive or worse with exercise), chronic cough (even if intermittent or nonproductive) and/or sputum production, and/or a history of COPD risk factors including a family history of COPD.¹

CLINICAL FEATURES

- COPD's three most common symptoms are cough, sputum production, and exertional dyspnea. In one study of newly diagnosed patients, most presented with cough (85%) and exertional dyspnea (70%); almost half (45%) reported increased sputum production.¹¹ Most patients were classified in GOLD stage 0 to 1 (42%) or 2 (46%) (see **Table 56-1**).
- Patients may also report chest tightness, often following exertion; fatigue, weight loss, and anorexia are symptoms later in the disease.
- Several validated questionnaires are available to assess symptoms in patients with COPD; GOLD recommends the Modified British Medical Research Council (MMRC) questionnaire (**Box 56-1**) or the 8-question COPD Assessment Test (CAT; <http://catestonline.org>).¹
- Physical findings may include:
 - Tobacco odor and nicotine staining of fingernails.
 - Increased expiratory phase or expiratory wheezing.
 - Signs of hyperinflation—Barrel chest, poor diaphragmatic excursion.
 - Use of accessory muscles of respiration—Intercostals, sternocleidomastoid, and scalene muscles.
 - Late in illness—Cyanosis of the lips and nail beds, wasting, and *cor pulmonale* (right-sided heart failure—signs include increased jugular-venous distention, right ventricular heave, third heart sound, ascites, and peripheral edema).

BOX 56-1 MMRC Dyspnea Scale

-
- 0 – Not troubled with breathlessness except with strenuous exercise.
 - 1 – Troubled by shortness of breath when hurrying on the level or walking up a slight hill.
 - 2 – Walks slower than people of the same age on the level because of breathlessness or has to stop for breath when walking at own pace on the level.
 - 3 – Stops for breath after walking about 100 yards or after a few minutes on the level.
 - 4 – Too breathless to leave the house or breathless when dressing or undressing.
-

LABORATORY TESTING

Postbronchodilator spirometry secures the diagnosis and provides the severity classification:^{1,12} **SOR B**

- At risk—Chronic cough and sputum production with normal spirometry.

Additional tests that may be useful in management are sputum culture (in acute exacerbations to assist in confirming pneumonia), complete blood count (to identify anemia or polycythemia), and blood gases (confirms hypoxia when peripheral oxygen saturation is <92% or respiratory failure [$\text{PCO}_2 >45$]).^{1,13}

- A serum level of α_1 -antitrypsin should be measured if you suspect a genetic mutation (young age at presentation [≤ 45 years], lower lobe emphysema, family history, minimal smoking history).
- Exercise (walking) tests to assess disability or response to rehabilitation.¹

IMAGING

A CXR is not useful for diagnosis but is helpful for excluding other diseases or identifying comorbidity (e.g., heart failure). Findings on CXR include:³

Hyperinflation manifested by the following (**Figures 56-1** to **56-3**):

- Increased anteroposterior (AP) diameter.
- Increased retrosternal air space.
- Infracardiac air.
- Low-set flattened diaphragms (best assessed in lateral chest).
- Vertical heart.
- Bullae are difficult to recognize in CXR but are easily seen on CT (**Figures 56-4** to **56-8**).
- Paucity of vascular markings in periphery (**Figure 56-2**).
- Pulmonary hypertension (CXR shows enlarged central pulmonary arteries).
- α_1 -Antitrypsin deficiency leads to early COPD even in nonsmokers. See **Figure 56-9** for advanced pulmonary emphysema in a 30-year-old woman with α_1 -antitrypsin deficiency. The CXR shows increased lung volumes, flattening of the diaphragms, and a vertical heart. A CT may show extensive panlobular emphysema of the mid and lower lung zones (**Figure 56-10**). The vascular markings are prominent in the upper lobes, demonstrating “cephalization” of flow.

A chest CT scan is the current definitive test for emphysema, but the findings do not influence treatment.⁶ Cystic and bullous lesions are better delineated with CT scan (**Figures 56-4**, **56-5**, and **56-7**), and collapsing airways with inspiration and expiration can also be demonstrated with CT. Chest CT is recommended if surgery is contemplated.¹

Echocardiography is suggested if features of cor pulmonale are present.¹³

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of an individual with persistent productive cough and dyspnea includes:

FIGURE 56-3 Posteroanterior (PA) radiograph showing flattened hemidiaphragms and decreased vascular markings from hyperinflation as a result of air trapping in a patient with COPD. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill; 2006:108, Figure 3-40 A and B. Copyright 2006.)

FIGURE 56-4 Lateral view in the patient in **Figure 56-2** showing increased anteroposterior (AP) diameter from hyperinflation as a result of air trapping in a patient with COPD. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill; 2006:108, Figure 3-40 A and B. Copyright 2006.)

- Asthma—Begins before age 40 years in most (often in childhood), usually episodic and characterized by increased responsiveness to stimuli (e.g., allergens, occupational exposures). Nocturnal awakenings with symptoms are common. This condition is reversible with bronchodilators (see Chapter 55, Asthma).
- Chronic bronchitis—A clinical diagnosis defined as the presence of cough and sputum production of at least 3 months in 2 consecutive years;¹ although often seen in patients with COPD and associated with development and/or acceleration of fixed airflow limitation, chronic bronchitis can occur in patients with normal spirometry.
- Pneumonia—Symptoms include fever, chills, and pleuritic chest pain; physical findings include dullness to percussion, bronchial breathing, egophony (E to A change), and crackles with area of infiltrate/pneumonia usually confirmed on CXR (see Chapter 53, Pneumonia).
- Tuberculosis—Any age; symptoms of chronic cough. CXR shows infiltrate; positive culture confirms (see Chapter 54, Tuberculosis).
- Congestive heart failure—Nonspecific basilar crackles; CXR shows cardiomegaly; echocardiogram confirms (see Chapter 48, Heart Failure).
- Lung cancer—Symptoms may occur with central or endobronchial growth of the tumor (e.g., cough, hemoptysis, wheeze, stridor, dyspnea), collapse of airways from tumor obstruction (e.g., post-obstructive pneumonitis), involvement of the pleura or chest wall (e.g., pleuritic chest pain), or from regional spread of the tumor (e.g., dysphagia, hoarseness from recurrent laryngeal nerve paralysis, dyspnea, and elevated hemidiaphragm from phrenic nerve paralysis). Findings on CXR or chest CT may be focal or unilateral and tissue confirms diagnosis (see Chapter 58, Lung Cancer).

Any of these processes/illnesses may occur in conjunction with emphysema.

MANAGEMENT

Management of COPD is based on symptoms, risk or history of exacerbations, and severity/predicted survival. GOLD places patients into four categories as shown in **Table 56-2**.

NONPHARMACOLOGIC

Nonpharmacologic therapies that should be considered for all patients are:^{1,5}

- Influenza and pneumococcal vaccination, which are most effective in the elderly. **SOR B** Also consider vaccination against herpes zoster as patients with COPD are at increased risk (adjusted hazard ratio [HR] 1.68, 95%CI, 1.45 to 1.95), especially if using inhaled steroids (adjusted HR 2.09, 95% CI, 1.38 to 3.16) or oral steroids (adjusted HR 3.00, 95% CI, 2.40 to 3.75).¹⁴
- Patient education (multidisciplinary and self-management training) improves patient outcomes and reduces costs and hospitalizations.^{1,15} **SOR A**
- Pulmonary rehabilitation programs decrease hospitalization at 6 to 12 months, increase quality of life, and improve dyspnea and exercise capacity.^{1,5} **SOR A** Pulmonary rehabilitation may increase survival and improve recovery following hospitalization.¹ **SOR B**

FIGURE 56-5 Centrilobular emphysema seen on high resolution CT of the chest. Diffuse emphysematous changes throughout both lungs are seen as darker round areas of cyst-like lesions. (Courtesy of Carlos S. Restrepo, MD.)

FIGURE 56-6 CT at the level of the aortic arch showing a pattern of cysts in the subpleural lung with an upper-lung zone predominance characteristic of mild paraseptal emphysema. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill; 2006:110, Figure 3-41 D. Copyright 2006.)

- There are no clear benefits of continuous positive pressure ventilation in patients with COPD unless they have coexisting sleep apnea, in which case there is an associated improvement in survival and decrease in risk of hospitalization.¹

For patients with an *acute exacerbation* of COPD (defined as an increase in symptoms and change in the amount and character of the sputum and anticipated to occur about 1 to 3 times a year in patients with moderate or severe COPD), the following assessments and non-pharmacologic interventions are recommended:^{1,13}

- Assess severity **SOR C**—Physical signs of a more severe exacerbation include use of accessory muscles of respiration, paradoxical chest wall movements, worsening (or new onset) cyanosis, new peripheral edema, hemodynamic instability, or worsening mental status. Consider pulse oximetry.
- Consider CXR for those with moderate to severe symptoms and focal lung findings to exclude other diagnoses.
- Consider an ECG if suspecting cardiac complication or comorbidity.
- Consider a complete blood count (to identify anemia, polycythemia, or leukocytosis) and a theophylline level if on theophylline at admission. Consider sputum or blood cultures if clinically appropriate (e.g., purulent sputum, fever).
- Consider blood gas for those with moderate to severe symptoms, advanced COPD, history of hypercarbia, or mental status changes.
- Hospitalize—Based on clinical judgment; recommended in those with marked increase in symptom intensity or onset of new physical signs (e.g., cyanosis); frequent exacerbations; older age; the presence of respiratory acidosis, hypercarbia, hypoxemia; severe underlying COPD or serious comorbidities (e.g., heart failure); failure to respond to outpatient treatment; or poor home support.¹ **SOR C**

MEDICATIONS

For patients with *stable COPD*, only smoking cessation and oxygen therapy for those with hypoxia at rest have been shown to improve outcome.¹ **SOR A**

- To assist with smoking cessation, consider nicotine replacement therapy (bupropion [150 mg, twice daily], varenicline [1 mg twice daily], nortriptyline [75 to 100 mg daily], or nicotine replacement [gum, inhaler, spray, patch]) and supportive counseling and follow-up; using these interventions improves rates of smoking cessation by up to 2-fold (see Chapter 236, Tobacco Addiction).^{1,16–18} **SOR A**
- Oxygen therapy is initiated for patients who have a resting O₂ saturation less than 89% (PaO₂ at or below 55 mm Hg [7.3 kPa], confirmed twice over a 3-week period or <89% in a patient with pulmonary hypertension or right-sided heart failure); chronic administration (<15 hours/day) in patients with chronic respiratory failure is associated with greater survival.¹ **SOR B**

The following are recommended for symptomatic relief:

- Short-acting inhaled bronchodilators— β -agonists (e.g., albuterol) or anticholinergic agents (e.g., ipratropium bromide)—intermittent use; **SOR A** these agents are comparable in efficacy and the choice of agent should be based on side effects, cost, and patient preference.¹
- Inhaled long-acting β -agonists (e.g., salmeterol, indacaterol)—Regular treatment is more effective, but more costly and may be associated

FIGURE 56-7 Close-up of CXR showing multiple large bullae in a patient with COPD. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill; 2006:111, Figure 3-42. Copyright 2006.)

FIGURE 56-8 CT scan of the patient in Figure 56-6 (at the level of the pulmonary veins) showing multiple large peripheral bullae; the patient was diagnosed with severe paraseptal emphysema. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill; 2006:111, Figure 3-42. Copyright 2006.)

FIGURE 56-9 Advanced pulmonary emphysema in a 30-year-old woman with α_1 -antitrypsin deficiency. The CXR shows increased lung volumes, flattening of the diaphragms, and a vertical heart. (Courtesy of Carlos S. Restrepo, MD.)

with tachycardia and tremor.¹ **SOR A** Salmeterol reduces the risk of hospitalization but has no effect on mortality or the rate of lung function decline. Adverse effects include tachycardia, tremor.

- Combination long-acting β -agonists with inhaled anticholinergic agents can provide incremental benefit for symptoms.¹ **SOR B** They may also be used in combination with inhaled corticosteroids to improve health status and reduce exacerbations in patients with moderate **SOR B** to severe COPD **SOR A**.¹
- Inhaled long-acting anticholinergic (tiotropium)—Tiotropium has a duration of action of 24 hours and reduces exacerbations and improves symptoms.¹ **SOR A** Adverse effects include dry mouth;¹ a recent metaanalysis concluded that mortality was increased with use of this medication (2.4% vs. 1.6% on placebo; number needed to harm over 1 year = 124).¹⁹
- Inhaled glucocorticoids—Regular use is associated with improved quality of life and a small decrease in the frequency of exacerbations (approximately half-a-day per month), but an increase in oral candidiasis, easy bruising, and bone loss (the latter shown for long-term triamcinolone acetonide).¹ **SOR A** These agents are recommended for patients with moderate to severe COPD or for frequent exacerbations. Parenteral steroids do not benefit patients with stable COPD. In a Cochrane review comparing inhaled glucocorticoids with long-acting β -agonists, the authors concluded that effects were comparable on most outcomes, including reduced frequency of exacerbation, with β -agonists conferring a small additional benefit in lung function while inhaled corticosteroid therapy showed a small advantage in health-related quality of life but increased the risk of pneumonia.²⁰

FIGURE 56-10 CT of the chest in the same 30-year-old woman with α_1 -antitrypsin deficiency. Coronal reformation of the CT demonstrates extensive panlobular emphysema of the mid and lower lung zones, which is a typical distribution of this condition. The vascular markings are more prominent in the upper lobes showing “cephalization” of flow. (Courtesy of Carlos S. Restrepo, MD.)

TABLE 56-2 Recommended Management of COPD Based on GOLD Grade and Exacerbation History

Patient Group	Description	Non-Pharmacological Treatment	Medications (First choice)
A	Few symptoms (MMRC grade 0-1 or CAT score <10) and 0-1 exacerbations per year, and/or mild impairment (GOLD 1 or 2)*	Smoking cessation, physical activity, vaccinations	Short-acting bronchodilator (anticholinergic OR beta2-agonist as needed)
B	More symptoms (MMRC ≥ 2 or CAT score ≥ 10) and 0-1 exacerbations per year; and or mild impairment (GOLD 1 or 2).*	Smoking cessation, physical activity, vaccinations, pulmonary rehabilitation	Long-acting bronchodilator (anticholinergic OR beta2-agonist)
C	Few symptoms (MMRC grade 0-1 or CAT score <10) and ≥ 2 exacerbations per year, and/or severe impairment (GOLD 3 or 4).*	Smoking cessation, physical activity, vaccinations, pulmonary rehabilitation	Inhaled corticosteroid AND Long acting bronchodilator (beta2-agonist OR anticholinergic)
D	More symptoms (MMRC ≥ 2 or CAT score ≥ 10) and ≥ 2 exacerbations per year, and/or severe impairment (GOLD 3 or 4).*	Smoking cessation, physical activity, vaccinations, pulmonary rehabilitation	Inhaled corticosteroid AND Long acting bronchodilator (beta2-agonist OR anticholinergic)

*See laboratory testing.

Abbreviations: MMRC = Modified British Medical Research Council; CAT = COPD Assessment Test; GOLD = Global Initiative for Chronic Obstructive Lung Disease.

- Theophylline—Mildly effective for symptoms **SOR A** and reduction in exacerbations **SOR B**, but associated with nausea and risk of toxicity with high blood levels.^{1,21}
- Mucolytic agents (e.g., guaifenesin, carbocysteine, potassium iodide)—Produce a small decrease in the frequency of exacerbations (0.5 fewer exacerbations/year) and in disability days.²² **SOR A** GOLD does not recommend these medications for routine use.¹
- Early investigation has begun on a phosphodiesterase-4 inhibitor (roflumilast) in patients with moderate to severe COPD already on an inhaled bronchodilator. There may be some improvement in exacerbations but other relevant patient outcome data are unevaluated; side effects include nausea, diarrhea, weight loss, and headache.²³

For patients with an acute exacerbation of COPD, the three classes of medications commonly used are bronchodilators, corticosteroids, and antibiotics.

- Inhaled bronchodilators—Both β -agonist and anticholinergics can be used alone or in combination; metered-dose inhalers with proper patient instruction perform as well as nebulized treatments and are less expensive; nebulizers can be considered for sicker patients.¹ **SOR A**
- Glucocorticoid—Use oral (prednisone 30 to 40 mg/day for 10 to 14 days) or intravenous glucocorticoids if the patient is unable to tolerate oral medication. Steroids decrease recovery time, hospital length of stay, and relapse rates.¹ **SOR A**
- Antibiotics—Treating COPD with antibiotics is controversial. In a systematic review, investigators found four placebo-controlled clinical trials and a metaanalysis that demonstrated significant improvements in outcome for patients treated with an antibiotic versus placebo.²⁴ In contrast, six studies failed to demonstrate statistical differences. GOLD recommends the use of antibiotics for 5 to 10 days for

patients with increased dyspnea, sputum volume, and sputum purulence, and for patients who require mechanical ventilation.¹ **SOR B** Antibiotics should also be considered for patients with increased purulent sputum and either increased sputum volume or dyspnea.¹ **SOR C**

- The choice of antibiotic does not appear to influence outcome and should be based on local bacterial resistance and severity of disease. For exacerbations of lesser severity, use narrow-spectrum antibiotics such as amoxicillin, doxycycline, or trimethoprim-sulfamethoxazole. For exacerbations of greater severity use broad-spectrum antibiotic such as azithromycin, amoxicillin-clavulanate, levofloxacin, cefuroxime axetil or hospitalize for IV antibiotics. **SOR C**
- Oxygen therapy—Use to maintain O₂ saturation above 88%.¹ **SOR C**
- Noninvasive mechanical ventilation (NIV) decreases mortality, decreases the need for intubation, and reduces hospital length of stay.¹ **SOR A** However, patients may find it difficult to tolerate. It should be considered for patients with moderate to severe dyspnea, moderate to severe acidosis (pH <7.35), hypercapnia (PaCO₂ >6.0 kPa, 45 mm Hg), and respiratory rate greater than 25 breaths/min.¹
- Mechanical ventilation support should be considered for patients with the above indications who are unable to tolerate NIV and for those with severe dyspnea, massive aspiration or inability to remove respiratory secretions, respiratory failure [life-threatening hypoxemia (PaO₂ <5.3 kPa, 40 mm Hg or PaO₂/FiO₂ <200 mm Hg), severe acidosis (pH <7.25) and hypercapnia (PaCO₂ > 8.0 kPa, 60 mm Hg)], heart rate less than 50 beats per minute with loss of alertness, severe ventricular arrhythmias, and respiratory arrest.¹ **SOR C**

COMPLEMENTARY AND ALTERNATIVE THERAPY

- There is supporting evidence for immunostimulant therapy (reduced hospital days), cineole (a constituent of eucalyptus oil on reducing severity and duration of exacerbations and improved lung function, dyspnea, and quality of life), and ginseng (on lung function and quality of life) in patients with COPD.^{25–27} **SOR B**
- Tai Chi and Qigong (twice weekly 60-minute sessions) significantly improved exercise tolerance and 3-month exacerbation rate compared with either exercise or no intervention in patients with COPD.²⁸ **SOR B**

SURGERY

Two surgical therapies with the best supporting evidence may be considered for patients with severe disease despite optimal medical therapy:

- Lung volume reduction surgery (LVRS)—Patients with upper lobe predominant disease and low postrehabilitation exercise capacity appear to gain the most symptom benefit.¹ LVRS in contrast to medical treatment improves survival (54% vs. 38.7%) in patients with severe upper-lobe emphysema and low postrehabilitation exercise capacity.¹ **SOR A**
- Lung transplantation—Considered for patients who are 65 years of age or younger with no comorbid disease. GOLD lists a BODE (body mass, obstruction, dyspnea, exercise index (see Prognosis) greater than 5 as an indication for transplantation.^{1,29} However,

investigators from Norway found no obvious survival benefit from lung transplantation in a cohort of 219 patients accepted onto the lung transplant waiting list.³⁰

REFERRAL

Reasons to consider referral include diagnostic uncertainty; severe disease, including onset of cor pulmonale; assessment for oxygen, corticosteroid, or pulmonary rehabilitation therapy; surgical assessment (bullous lung disease, severe disease); rapid decline in FEV₁; early onset or family history of COPD; frequent infections; and hemoptysis.¹³ There are new treatments for α_1 -antitrypsin deficiency and these patients should be referred to a pulmonologist for evaluation and treatment.

PREVENTION AND SCREENING

- The best prevention for COPD is to not smoke or to quit smoking. Limiting occupational exposures and exposure to indoor air pollution is also preventive.
- GOLD recommends active case finding but not general population screening.¹ The U.S. Preventive Services Task Force also recommends against screening adults for COPD using spirometry.³¹

PROGNOSIS

- In a longitudinal study of 227 patients with COPD in Japan, 5-year survival was 73%; level of dyspnea and not FEV₁ was correlated with survival rates.³²
- Severity classification (see “Laboratory Testing” above) can be used in predicting risk of exacerbations (1.1 to 1.3 for severe and 1.2 to 2.0 for very severe), hospitalizations per year (0.11 to 0.2 for moderate, 0.25 to 0.3 for severe, and 0.4 to 0.54 for very severe), or 3-year mortality (11% for moderate, 15% for severe, 24% for very severe).¹
- The BODE index is a composite measure using body mass, obstruction (FEV₁, % predicted), dyspnea (MMRC score), and exercise (6-minute walking distance) to predict mortality. The risk of death from respiratory causes increases by more than 60% for each 1 point increase in BODE score.³³ An online calculator is available at <http://www.newleaf.com/ns/c/calculator-bode.htm?storeID=j3qsseqx5cs92j2000akhmccqja05t39> (accessed January 2012).
- In-hospital mortality of patients admitted for hypercapnic exacerbation with acidosis is approximately 10% and mortality at 1-year postdischarge for those requiring mechanical ventilation is 40%.¹

FOLLOW-UP

Patients should be followed regularly for disease progression or development of complications.

- At each visit ask about symptoms, activity, and sleep. For smokers, encourage cessation. Symptom questionnaires can be used (every 2 to 3 months suggested by GOLD) for monitoring.

- Spirometry is recommended by GOLD at least yearly.¹ **SOR** 
- For patients on medications, monitor treatment effectiveness (“have you noticed a difference, for example less breathlessness”) and side effects. Observe inhaler technique at least once to ensure optimal delivery.
- Document exacerbations/hospitalizations; this may indicate a need for additional treatment.
- Monitor for comorbidities (e.g., heart disease, hypertension, osteoporosis, anxiety/depression, lung cancer, infections, metabolic syndrome, and diabetes) and maximize control of those conditions. The GOLD reference provides information on management of these conditions in patients with COPD.¹
- Additional concerns for patients with severe COPD include need for long-term oxygen, need for specialist referral, including social services; biyearly evaluation should be considered.¹³ Hospice referral may also be appropriate.

PATIENT EDUCATION

Smoking cessation should be strongly and repeatedly encouraged. Progressive exercise should also be encouraged, activities that brace the arms and allow use of accessory muscles of respiration are better tolerated—these include pushing a cart, walker, or wheelchair, and use of a treadmill.

57 PULMONARY EMBOLUS

Mindy A. Smith, MD, MS

PATIENT STORY

A 52-year-old woman developed acute shortness of breath 3 weeks after a hysterectomy. She denied leg pain or swelling. She has no chronic medical problems and takes no medications. Her pulse is 105 beats/min, respiratory rate is 20 breaths/min, and the rest of her examination is unremarkable. She had an elevated hemidiaphragm on chest X-ray (CXR). These findings placed her at moderate risk for pulmonary embolism (PE) based on the Geneva score. Chest CT demonstrated a moderate-sized PE similar to the one shown in **Figure 57-1**. She was treated with anticoagulation without complications.

INTRODUCTION

PE is a thromboembolic occlusion (total or partial) of one or more pulmonary arteries, usually arising from a deep venous thrombosis (DVT).

EPIDEMIOLOGY

- Population estimate of the age- and sex-adjusted annual incidence of DVT is 48 per 100,000 and 69 per 100,000 for PE; the incidence increases with age.¹
- PEs are noted as incidental findings in 1% to 4% of chest CT studies.²
- One metaanalysis concluded that nearly 1 in every 4 to 5 patients presenting with an exacerbation of chronic obstructive pulmonary disease has a PE; presenting signs and symptoms did not distinguish patients with and without PE.³
- In a metaanalysis of randomized controlled trials (RCTs) of patients on venous thromboembolism (VTE) prophylaxis, the pooled rates of symptomatic DVT were 0.63% (95% confidence interval [CI], 0.47% to 0.78%) following knee arthroplasty and 0.26% (95% CI, 0.14% to 0.37%) following hip arthroplasty. The pooled rates for PE were 0.27% (95% CI, 0.16% to 0.38%) following knee arthroplasty and 0.14% (95% CI, 0.07% to 0.21%) following hip arthroplasty.⁴

ETIOLOGY AND PATHOPHYSIOLOGY

- PE is most commonly caused by embolization of a thrombus from a proximal leg or pelvic vein that enters the pulmonary artery circulation and obstructs a vessel. PE may also be caused by:¹
 - An upper-extremity thrombus (from indwelling catheters or pacemakers) (**Figure 57-1**).
 - Fat embolus (following surgery or trauma).
 - Hair/talc/cotton embolus (from intravenous drug use).
 - Amniotic fluid embolus (from a tear at the placental margin in a pregnant woman).

FIGURE 57-1 CXR showing a wedge-shaped pulmonary infarction with the base on the pleural surface and the apex at the tip of a pulmonary artery catheter; the catheter caused the occlusion of a peripheral artery. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill; 2006:272, Figure 5-61. Copyright 2006.)

- PE results from vascular endothelial injury, which promotes platelet adhesion, blood flow stasis, and/or hypercoagulation causing more coagulants to accumulate than usual and resulting obstruction. Although most PEs are asymptomatic and do not alter physiology, PE can cause:
 - Increased pulmonary, vascular, and airway resistance (from obstruction of vessels or distal airways).
 - Impaired gas exchange (from increased dead space and right to left shunting).
 - Alveolar hyperventilation (from stimulation of irritant receptors).
 - Decreased pulmonary compliance (from lung edema, hemorrhage, or loss of surfactant).
 - Right ventricular (RV) dysfunction (from increased pulmonary vascular resistance, increased RV wall tension, and reduced right coronary artery flow).
 - Only approximately 10% of emboli cause pulmonary infarction; most PEs are multiple and involve the lower lobes.⁵

RISK FACTORS

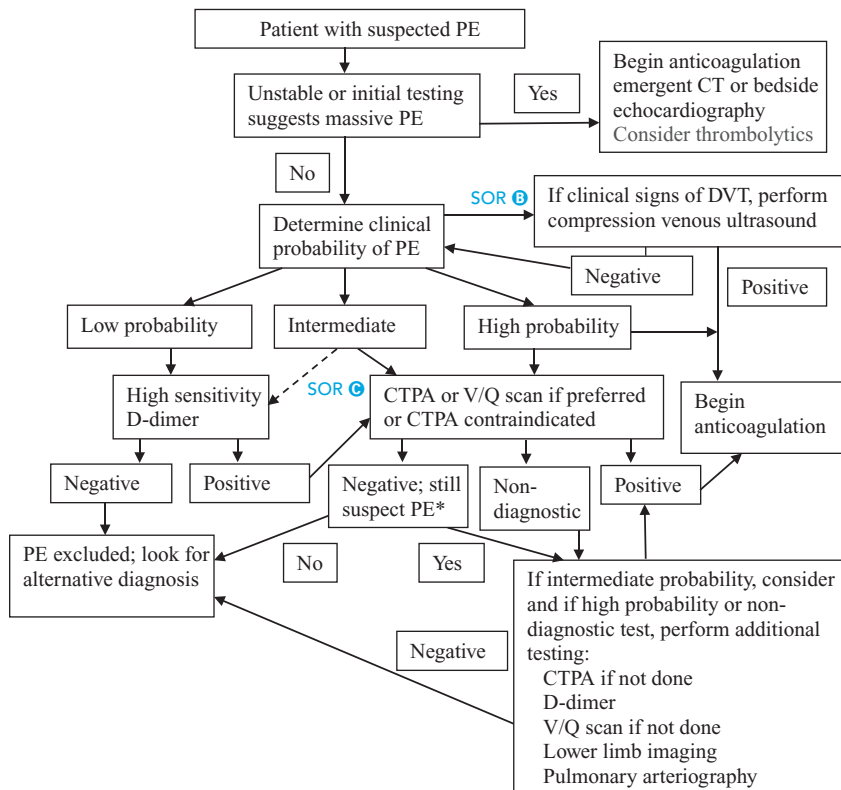

In a population study, independent risk factors for DVT included:⁶

- Surgery (odds ratio [OR], 21.7; 95% CI, 9.4 to 49.9).
- Trauma (OR, 12.7; 95% CI, 4.1 to 39.7).
- Hospital or nursing home confinement (OR, 8.0; 95% CI, 4.5 to 14.2).
- Malignant neoplasm with (OR, 6.5; 95% CI, 2.1 to 20.2) or without (OR, 4.1; 95% CI, 1.9 to 8.5) chemotherapy.
- Central venous catheter or pacemaker (OR, 5.6; 95% CI, 1.6 to 19.6).
- Superficial vein thrombosis (OR, 4.3; 95% CI, 1.8 to 10.6). A recent study found a slightly higher OR, 6.3 (95% CI, 5.0 to 8.0) for DVT and 3.9 (95% CI, 3.0 to 5.1) for PE.⁷
- Neurologic disease with extremity paresis (OR, 3.0; 95% CI, 1.3 to 7.4).
- Other risk factors for PE include hormonal treatment (i.e., combined estrogen/progestogen oral contraceptives [OCs] or menopausal hormone therapy), pregnancy, obesity, smoking, chronic obstructive pulmonary disease, immobility, bed rest for more than 3 days, and clotting disorders. In a Danish population study, the risk of venous thrombosis in current users of combined OCs decreased with duration of use (OR <1 year 4.17 [95% CI, 3.73 to 4.66]; OR 1 to 4 years 2.98 [95% CI, 2.73 to 3.26] and OR >4 years 2.76 [95% CI, 2.53 to 3.02]) and decreasing oestrogen dose.⁸ OCs with desogestrel, gestodene, or drospirenone were associated with a significantly higher risk of venous thrombosis than those with levonorgestrel, while progestogen-only pills and hormone-releasing intrauterine devices were not associated with an increased risk.
- Genetic predisposition includes factor V Leiden and prothrombin gene mutations.
- Use of an antipsychotic agent (particularly atypical antipsychotics) increased risk of DVT in a population nested case-control study (OR 1.32, 95% CI, 1.23 to 1.42).⁹

DIAGNOSIS

A history and physical examination should be completed to assess risk factors and determine whether the patient is clinically stable. If unstable (e.g., hemodynamic instability [including systolic blood pressure <90 mm Hg, or a drop of 40 mm Hg], syncope, severe hypoxemia, or respiratory distress), thrombolytic therapy should be considered (Figure 57-1).^{2,10}

Diagnostic strategy begins with the determination of a patient's (pretest) probability of PE using a clinical decision rule (Figure 57-2). The two most frequently used rules are the Geneva and the Wells score.^{11,12} Online calculators are available for the Wells score (<http://www.mdcalc.com/wells-criteria-for-pulmonary-embolism-pe/>). The Geneva score appears to be the most consistent across experience of examiner;¹³ and the revised Geneva scoring system performs as well

*Based on clinical impression, high probability with positive D-dimer and negative CTPA, or confusing presentation.

FIGURE 57-2 Approach to the patient with suspected pulmonary embolus. *Abbreviations:* CT, computed tomography; CTPA, computed tomographic pulmonary arteriography; DVT, deep venous thrombosis; PE, pulmonary embolism; V/Q, ventilation-perfusion. (Dotted lines indicate differences in guidelines). (Information from Fesmire FM, Brown MD, Espinosa JA, et al.; American College of Emergency Physicians. Critical issues in the evaluation and management of adult patients presenting to the emergency department with suspected pulmonary embolism. *Ann Emerg Med.* 2011;57(6):628-652; Institute for Clinical Systems Improvement (ICS). *Venous Thromboembolism Diagnosis and Treatment.* Bloomington, MN: Institute for Clinical Systems Improvement (ICS); 2011 Mar. 93 p. Available at <http://www.guideline.gov/content.aspx?id=32482&search=pulmonary+embolism>.)

as the Wells and does not require laboratory testing or imaging.¹⁴ A score of 0 to 3 indicates a low probability of PE (8%); 4 to 10 indicates intermediate probability of PE (28%); and greater than 10 indicates a high probability of PE (74%). The revised Geneva score is derived by summing the following points:

- Age older than 65 years (+1).
- Previous DVT or PE (+3).
- Surgery or fracture within 1 month (+2).
- Active malignant condition (+2).
- Unilateral lower limb pain (+3).
- Hemoptysis (+2).
- Heart rate 75 to 94 beats/min (+3) or equal to or greater than 95 beats/min (+5).
- Pain on lower-limb deep venous palpation and unilateral edema (+4).

The Wells score is derived by summing the factors below; a score less than 2 indicates a low probability of PE (15%); 2 to 6 indicates intermediate probability of PE (29%); and greater than 6 indicates a high probability of PE (59%). Alternatively, the Wells score can be dichotomized as PE less likely or likely (the latter with score >4):²

- Clinically suspected DVT (+3).
- Alternative diagnosis is less likely than PE (+3).
- Tachycardia (+1.5).
- Immobilization/surgery in previous 4 weeks (+1.5).
- History of DVT or PE (+1.5).
- Hemoptysis (+1.0).
- Malignancy (treatment for within 6 months, palliative) (+1.0).

Patients with a high pretest probability of PE or high risk because of comorbidities (e.g., pulmonary hypertension) should be started on anticoagulation during the workup.^{2,10}

CLINICAL FEATURES

- Dyspnea—The most common symptom; tachycardia is the most common sign. Sudden onset of dyspnea is the best single predictor (positive likelihood ratio [LR+] 2.7).
- Chest pain—May be caused by a small, peripheral PE with pulmonary infarction.
- Other signs—Include fever, neck vein distention, and accentuated pulmonic component of the second heart sound.
- Massive PE—May present with shock, syncope, and cyanosis.

LABORATORY STUDIES AND ECG

- The combination of clinical decision rules and sensitive plasma D-dimer is used to rule out a PE (sensitive but not specific).^{15,16}
SOR B The test is suggested for patients with a low or moderate probability of a PE: if low probability and negative (<500 ng/mL), there is only approximately a 0.4% chance that the patient has a PE.¹⁴ If low or intermediate probability, a negative D-dimer concentration is associated with a posttest probability of PE below 5% (negative likelihood ratio [LR−] 0.08 [0.04 to 0.18]).¹⁷ Of patients with a PE, 90% will have a value greater than 500 ng/mL. Use of

an age-adjusted D-dimer (patient's age \times 10 mcg/L) was shown in one study to increase the percentage of patients in whom PE could be safely excluded (from 13% to 14% to 19% to 22%).¹⁸ If the D-dimer is positive, further testing is needed (**Figure 57-2**).²

- An ECG may be indicated to search for alternative diagnoses. The most frequent, sensitive, and specific ECG finding for PE is T-wave inversion in leads V1 to V4, which is indicative of RV strain. Other findings include tachycardia, new-onset atrial fibrillation or flutter, S in Lead I, Q and inverted T in lead III, and a QRS axis greater than 90 degrees.
- Arterial blood gas is obtained if clinically indicated. A platelet count should be obtained prior to initiation of fondaparinux.¹⁰

IMAGING

- CXR is often nonspecific; dyspnea with a near normal CXR should suggest PE. Findings that may be seen on CXR include:
 - Triad of basal infiltrate, blunted costophrenic angle, and elevated hemidiaphragm.
 - Infiltrates similar to pneumonia (**Figure 57-3**) that may be diagnosed using CT (**Figure 57-4**).
 - A peripheral wedge-shaped density (**Figure 57-1**).
 - Decreased vascular markings (**Figure 57-5**).
 - When a patient has an intermediate or high PE probability score, PE is confirmed by a positive CT pulmonary angiography (CTPA) or high-probability lung scan, and ruled out by a negative CTPA or normal lung scan (**Figure 57-1**). The American College of Radiology (ACR) and Institute for Clinical Systems Improvement recommend CTPA over ventilation–perfusion (V/Q) scan for patients with suspected PE, unless the former is contraindicated or nondiagnostic (**Figure 57-1**).^{2,19} CT (**Figure 57-4**) can also provide evidence of alternate diagnoses.
 - A V/Q scan is considered the initial test for patients with high probability of PE who have renal insufficiency or dye allergy. A high-probability scan for PE (positive predictive value of 90%) has 2 or more segmental perfusion defects with normal ventilation.
 - For pregnant women with suspected PE, the American Thoracic Society/Society of Thoracic Radiology recommend CXR as the initial study followed by lung scintigraphy (V/Q scan) if the CXR is normal, and CTPA if the V/Q scan is nondiagnostic.²⁰
 - If the CTPA or lung scan is nondiagnostic, a leg ultrasound with compression is usually performed. If positive for a DVT, proceed with treatment as below. If normal or nondiagnostic, other testing such as a pulmonary angiogram is suggested (**Figure 57-1**).
 - Pulmonary angiography is generally reserved for patients with nondiagnostic CTPA, lung scans, or leg ultrasound, and for patients who will undergo embolectomy or catheter-directed thrombolysis. ACR also recommends pulmonary angiography in circumstances where a specific diagnosis (i.e., PE) is considered necessary for the proper patient management and before placement of an inferior vena cava (IVC) filter.¹⁰ An intraluminal filling defect may be seen along with truncated arteries associated with regions of diminished perfusion (**Figure 57-6**).
 - Although MRI is not indicated in the routine evaluation of suspected PE, magnetic resonance angiography (MRA) is used in certain centers with particular interest and expertise, and in patients in whom contrast administration for CTPA or

FIGURE 57-3 CXR showing bilateral pulmonary infiltrates thought to represent pneumonia. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill; 2006:273, Figure 5-63 A. Copyright 2006.)

FIGURE 57-4 CT scan from the patient in **Figure 57-2** demonstrates several large, wedge-shaped pulmonary opacities with air bronchograms characteristic of pulmonary infarcts. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill; 2006:273, Figure 5-63 B. Copyright 2006.)

pulmonary angiography is thought to be contraindicated because of renal failure, prior reaction to iodinated contrast, pulmonary hypertension, or for other reasons.¹⁹

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of a symptomatic PE includes:

- **Pneumonia**—Symptoms include chills, fever, and pleuritic chest pain (the latter two can occur with PE); physical findings include dullness to percussion, bronchial breathing, egophony (E-to-A change), and crackles with area of infiltrate/pneumonia usually confirmed on CXR (see Chapter 53, Pneumonia).
- **Congestive heart failure**—History of previous heart failure or myocardial infarction; symptoms of paroxysmal nocturnal dyspnea, orthopnea, or the presence of bilateral lower extremity edema, third heart sound, hepatjugular reflex, and jugular venous distention. CXR may show pulmonary venous congestion, interstitial or alveolar edema, and cardiomegaly (see Chapter 48, Heart Failure).
- **Pneumothorax**—History of previous pneumothorax or chronic obstructive pulmonary disease, or current rib fracture; physical findings include absence of breath sounds and CXR may show free air, an elevated hemidiaphragm, or a shift of the mediastinum to the contralateral side with a tension pneumothorax.

MANAGEMENT

NONPHARMACOLOGIC

- Knee-high compression stockings (30 to 40 mm Hg) are recommended to reduce recurrence and prevent post-thrombotic syndrome.¹⁰ **SOR A**
- Psychological support may be needed.

MEDICATION

- Primary treatment of PE is considered for patients with hemodynamic instability, RV dysfunction, or infarct. In selected patients with massive PE, systemic administration of thrombolytic therapy (via a peripheral vein with a 2-hour infusion) is suggested.^{2,10} **SOR B** Brain natriuretic peptide and troponin testing, combined with echocardiography, can help identify patients at high risk of deterioration who would be candidates for thrombolytic therapy.²
- Moderate to large PE may be treated similarly or with anticoagulation only. In a recent Cochrane review, the authors found no trials comparing thrombolytic therapy to surgical intervention and were unable to determine whether thrombolytic therapy was better than heparin for PE.²¹
- Acute PEs or proximal DVT are treated with oral anticoagulation to prevent future PEs. In addition to beginning oral anticoagulation (e.g., warfarin 5 mg daily, adjusted based on international normalized ratio [INR]), treatment options include intravenous unfractionated heparin (UFH) using a weight-based nomogram, SQ low-molecular-weight heparin (LMWH; 1 mg/kg twice daily) or SQ fondaparinux (a selective factor Xa inhibitor) for a minimum of 5 days.^{2,10} **SOR A** The American College of Chest

FIGURE 57-5 Pulmonary embolism: Westermark sign, an avascular zone because of obstructed vessel from a blood clot. In this patient, both lung apices and the mid to lower thorax have decreased vascular markings. Note the fusiform enlargement of both hila and the prominent pulmonary artery mediastinal shadow characteristic of pulmonary hypertension. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill; 2006:748, Figure 14-19 A. Copyright 2006.)

FIGURE 57-6 Pulmonary angiogram in the patient in Figure 57-4 showing abruptly truncated pulmonary arteries associated with regions of diminished perfusion typical of chronic pulmonary emboli. (From Miller WT Jr. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill; 2006:748, Figure 14-19 B. Copyright 2006.)

Physicians (ACCP) recommends LMWH as first choice unless there is a massive PE, concern about SQ absorption, severe renal insufficiency, or thrombolytic therapy is under consideration or planned; IV UFH is then the preferred agent.¹⁰ If UFH is used, therapeutic levels (activated partial thromboplastin time [aPTT] 1.5 to 2.5 times normal) should be achieved within 24 hours.²²

- Once the INR is therapeutic (range: 2 to 3) for at least 24 hours prior to discontinuing above treatment, oral anticoagulation is continued for a minimum of 3 to 12 months or indefinitely unless there is a known reversible or time-limited risk factor (e.g., recent surgery) when oral anticoagulation may be discontinued after 3 months.^{2,10} **SOR A** For additional recommendations on duration of therapy, see the ACCP guideline.¹⁰ A Cochrane review reported no excess recurrence of VTE after stopping therapy and while absolute risk of recurrence declines over time, the risk for major bleeding remains.²³
- In another Cochrane review based on 15 RCTs, fixed-dose SQ UFH could not be proven non-inferior to standard treatment with respect to DVT and PE at 3 months (trend favored standard arm), but was safe and effective with regard to rates of major bleeding and death.²⁴
- Patients with a history of heparin-induced thrombocytopenia (HIT) should not be treated with either UFH or LMWH. Fondaparinux is an option, although several cases of fondaparinux-associated HIT have been reported.¹⁰
- Direct thrombin inhibitors (e.g., ximelagatran) appear to be as effective as LMWH in prevention of VTE and treatment of PE, may have fewer side effects, and do not require routine monitoring. They are not considered initial therapy using current guidelines. In one trial, idraparinux was not as effective as heparin for PE treatment.²⁵ In another trial, oral ximelagatran was as effective as enoxaparin followed by warfarin in patients with PE.²⁶

SURGERY AND PROCEDURES

Highly compromised patients who are unable to receive thrombolytic therapy or whose critical status does not allow sufficient time to infuse thrombolytic therapy may be treated with pulmonary embolectomy.¹⁰

SOR C In a Japanese case series of 19 patients undergoing embolectomy, most for massive or submassive PEs in the main pulmonary trunk or bilateral main pulmonary arteries, operative mortality was 5.3%.²⁷ No patients exhibited newly developed neurologic damage.

- IVC filter placement is reserved for patients with contraindications to anticoagulation or for failure of anticoagulation (i.e., recurrence or progression of thromboembolism despite anticoagulation).^{2,10} **SOR C** Although they decrease recurrent PE, they do not appear to improve long-term survival.
- Adjunctive therapy, if needed, includes pain relief and supplemental oxygen. RV failure/shock may be treated with dobutamine.

REFERRAL OR HOSPITALIZATION

- Consider consultation with a coagulation specialist for patients with recurrent VTE, if alternative anticoagulants are being considered, if there is an increased risk of bleeding, and for pregnant women.
- Patients with cardiovascular or respiratory compromise should be admitted to the intensive care unit. Patients with symptomatic PE

are usually hospitalized because of decreased cardiopulmonary reserve.¹⁰ One open-label trial (N = 344) found no significant differences between inpatient and outpatient treatment with only 1 patient dying in each group.²⁸ However, 2 outpatients had major bleeding in the first 14 days and 3 by 90 days versus no patients in the inpatient group.

PREVENTION

- Mechanical methods (graduated compression stockings [GCS] and/or intermittent pneumatic compression) are recommended for thromboprophylaxis in hospitalized patients who are at high risk of bleeding or possibly as an adjunct to anticoagulant-based prophylaxis.¹⁰ **SOR A** For more detailed information on prophylaxis (e.g., surgical or cancer patients), see the ACCP guidelines.
- A Cochrane review found GCS effective in reducing the risk of DVT in hospitalized patients from 26% without GCS to 13% with GCS and from 16% with another method of prophylaxis alone to 4% with GCS with another method of prophylaxis.²⁹
- The American College of Physicians recommends assessment of the risk for thromboembolism and bleeding and pharmacologic prophylaxis with heparin or a related drug unless the assessed risk for bleeding outweighs the likely benefits for hospitalized nonsurgical patients. They recommend against use of GCS for routine hospitalized nonsurgical patients.³⁰
- For long-distance travelers (e.g., flights >8 hours) avoidance of constrictive clothing around the lower extremities or waist, maintenance of adequate hydration, and frequent calf muscle contraction are recommended.¹⁰ **SOR C** In high-risk individuals, consider use of GCS providing 15 to 30 mm Hg of pressure at the ankle or a single prophylactic dose of LMWH, injected prior to departure.¹⁰ **SOR C**

PROGNOSIS

- In a large multicenter study of patients with acute PE (N = 1880), mortality rate directly attributed to PE was 1% (95% CI, 0% to 1.6%).³¹ Mortality from hemorrhage was 0.2% and the all-cause 30-day mortality rate was 5.4% (95% CI, 4.4% to 6.6%). Delay in initiating anticoagulation appeared to be a mortality factor as only 3 of 20 patients with fatal PE had systemic anticoagulation initiated before diagnostic confirmation; another 3 of these 20 received a fibrinolytic agent. These figures were much improved over a 3-country registry of patients (N = 2110) with acute PE from 1999 where the 3-month mortality rate was 15.3%.³²
- In a retrospective Japanese study of patients with PE treated surgically, the 10-year survival rate was 83.5% ± 8.7%.²⁹
- In one study with a rate of adverse events of 7.4% (N = 42) at 30 days following acute PE, factors associated with those events included altered mental state (OR 6.8; 95% CI, 2.0 to 23.3), shock on admission (OR 2.8; 95% CI, 1.1 to 7.5), and cancer (OR 2.9; 95% CI, 1.2 to 6.9).³³
- In an Italian prospective cohort study of patients with DVT or PE following discontinuation of anticoagulation therapy (N = 1626), 22.9% had a recurrence of VTE.³⁴

- Pulmonary hypertension develops in approximately 5% of patients following PE.³⁵

FOLLOW-UP

- Patients on warfarin should be monitored using a standard protocol. Patients on LMWH do not require routine monitoring except for pregnant women where monitoring with anti-Xa levels is recommended.¹⁰ **SOR C**
- For patients with serious bleeding complications, management includes holding warfarin, giving vitamin K₁ 10 mg slow IV plus fresh-frozen plasma or prothrombin complex concentrate, and repeating vitamin K₁ every 12 hours as needed. **SOR C**
- PE is slow to resolve; based on 4 imaging studies, the percentage of patients with residual pulmonary thrombi was 87% at 8 days after diagnosis, 68% after 6 weeks, 65% after 3 months, 57% after 6 months, and 52% after 11 months.³⁶

PATIENT EDUCATION

- Patients taking warfarin should be instructed about the importance of remaining on oral anticoagulation for at least 3 months and use of compression stockings to decrease the likelihood of recurrence. Patients should also be counseled about the signs and symptoms of bleeding, to ask about potential drug interactions before starting a new medication, and the importance of laboratory monitoring.
- Use of an anticoagulation service or home self-monitoring³⁷ may be considered to improve adherence and reduce complications.
- Avoidance of periods of prolonged immobilization is suggested.

58 LUNG CANCER

Mindy A. Smith, MD, MS

PATIENT STORY

A 60-year-old woman presents with a solid, nontender, movable mass on her upper chest that's been there for 6 months. It began as a dime-size mass and has been growing more rapidly over the past month (**Figure 58-1A**). She has lost 10 pounds over the last year without dieting. She has smoked 1 pack of cigarettes per day since age 18 years and gets short of breath easily. Her “smoker’s cough” has gotten worse in the last few months and occasionally she coughs up some blood-tinged sputum. Her family physician excised the mass in the office and sent it to pathology (**Figure 58-1B**). When the result demonstrated squamous cell carcinoma of the lung, a chest x-ray (CXR) was ordered (**Figure 58-2A**). The radiologist suggested a CT to confirm the diagnosis (**Figure 58-2B**). The patient chose to have no treatment and passed away in 10 months of her lung cancer.

INTRODUCTION

Lung cancer is a malignant neoplasm of the lung arising from respiratory epithelium (bronchi, bronchioles/alveoli), most commonly adenocarcinoma or squamous cell carcinoma.

EPIDEMIOLOGY

- In 2007, lung cancer was diagnosed in 203,546 people in the United States (109,643 men and 93,893 women).¹ Both incidence and mortality rates have been decreasing since 1999 for men, but remain level for women.
- Black men have the highest age-adjusted incidence rates (99.8/100,000) followed by white men (75.3/100,000), and then black women (54.7/100,000) and white women (54.6/100,000); Hispanic men (41.5/100,000) and women (26.1/100,000) have the lowest incidence rates.²
- Risk increases with age; at age 60 years, 2.29% of men will develop lung cancer in 10 years and 5.64% in 20 years.¹ Among women at age 60 years, 1.74% will develop lung cancer in 10 years and 4.27% in 20 years. Median age at diagnosis is 71 years.²
- In 2007, lung cancer was the leading cause of cancer deaths, accounting for 14% of all cancer diagnoses and 28% of all cancer deaths.³
- The 2011 estimate for new cases of lung cancer in the United States was 221,130 with 156,940 deaths from the disease.⁴

ETIOLOGY AND PATHOPHYSIOLOGY

- Lung cancer begins in the lungs spreading to regional lymph nodes and regional structures (e.g., trachea, esophagus). Extrathoracic

FIGURE 58-1 A. Growing chest nodule in a 60-year-old woman who smoked tobacco her whole adult life. The pathology demonstrated metastatic squamous cell carcinoma from the lung. B. The resected nodule was surgically removed by the family physician in the office. (Courtesy of Leonard Chow, MD, and Ross Lawler, MD.)

metastases are common (found at autopsy in 50% to 95%) and sites include brain, bone, and liver.⁵

- Likely caused by a multistep process involving both carcinogens and tumor promoters; a number of genetic mutations (e.g., epidermal growth factor receptor [EGFR] mutations) are present in lung cancer cells, including activation of dominant oncogenes and inactivation of tumor-suppressor oncogenes.⁵
- There are two main groupings of lung cancer: non–small cell lung cancer (NSCLC; most common) and small cell lung cancer (SCLC). The four major cell types responsible for 88% of cases⁵ are:
 - Adenocarcinoma (including bronchoalveolar)—32% of cases.
 - Squamous or epidermoid carcinoma—29% of cases.
 - Small cell (or oat cell) carcinoma—18% of cases.
 - Large cell (or large cell anaplastic)—9% of cases.
- Adenocarcinoma, squamous carcinoma, and large cell are classified together under NSCLC because of similar diagnostic, staging, and treatment approaches.⁴
- Adenocarcinoma and squamous carcinoma have defined premalignant precursor lesions with lung tissue morphology ranging from hyperplasia to dysplasia and carcinoma in situ.³

RISK FACTORS

- Smoking is the major risk factor; a smoking history (current or former) is present in 90%, with a relative risk ratio of 13 (passive smoke exposure has a risk ratio of 1.5).³ Currently, 28% of men, 25% of women, and 38% of high school seniors smoke in the United States. Women have a higher susceptibility to the carcinogens in tobacco (Chapter 236, Tobacco Addiction).
- Occupations and exposures that increase risk of lung cancer include asbestos mining and processing, welding, pesticide manufacturing (arsenic), metallurgy (chromium), polycyclic hydrocarbons (through coke oven emissions), iron oxide, vinyl chloride, and uranium.³ Home exposure to asbestos or radon and diesel exhaust also increase risk.^{2,6}
- Radiation therapy to the breast or chest.⁴
- Family history of lung cancer.
- Beta-carotene supplementation in current smokers (small increased risk).
- Hormone therapy (women). In the Women's Health Initiative, although incidence of lung cancer was not significantly increased, death from lung cancer (primarily NSCLC) was increased (73 vs. 40 deaths; 0.11% vs. 0.06%).⁷

DIAGNOSIS

Signs and symptoms depend on location, tumor size and type, and the presence of local or distant spread.

- Five percent to 15% of patients are asymptomatic—The cancer is found on chest imaging performed for another reason.⁵
- Systemic symptoms (e.g., anorexia, cachexia, weight loss [seen in 30% of patients]) may be seen, but the cause is unknown.

FIGURE 58-2 A. Chest x-ray showing squamous cell carcinoma of the lung. B. CT scan demonstrating the architecture of the squamous cell carcinoma of the lung. (Courtesy of David A. Kasper DO, MBA.)

The diagnosis of lung cancer requires tissue confirmation through the safest and least-invasive procedure. Procedures include sputum cytology, bronchoscopy, lymph node biopsy, operative specimen, needle aspiration (e.g., endobronchial ultrasound-guided transbronchial approach for mediastinal or hilar lymph nodes or CT-guided transthoracic approach for peripheral tumors), biopsy under CT guidance, or cell block from pleural effusion.^{5,8}

- Immunohistochemistry (e.g., thyroid transcription factor 1 for adenocarcinoma or P63 for squamous carcinoma) is now being used to help differentiate between cell types when morphologic criteria used in resections are not apparent.⁸ Differentiation is important as different cell types respond differently to treatment.
- For suspicious central lung lesions, sputum cytology (at least three specimens) is a reasonable first step followed by bronchoscopy if needed.⁵ **SOR B**
- In patients with a suspicious peripheral lung lesion (especially <2 cm), if sputum cytology fails to confirm the diagnosis, transthoracic needle aspiration has a higher sensitivity than bronchoscopy.⁵ **SOR A**
- In patients with a lesion that is moderately suspicious for lung cancer who appear to have limited disease, excisional biopsy and subsequent lobectomy if a lung cancer is confirmed is recommended.⁵ **SOR B**

CLINICAL FEATURES

- The most common symptoms at diagnosis are worsening cough or chest pain.⁴ Symptoms may occur in the following situations:⁵
 - Central or endobronchial growth of the tumor may produce cough, hemoptysis, wheezing, stridor, and dyspnea.
 - Collapse of airways from tumor obstruction may cause post-obstructive pneumonitis.
 - Involvement of the pleura or chest wall may cause pleuritic chest pain, dyspnea on a restrictive basis, or lung abscess from tumor cavitation.
 - Regional spread of the tumor may cause tracheal obstruction; dysphagia from esophageal spread; hoarseness from recurrent laryngeal nerve paralysis; dyspnea and elevated hemidiaphragm from phrenic nerve paralysis; and Horner syndrome (enophthalmos, ptosis, miosis, ipsilateral loss of sweating from sympathetic nerve paralysis).
 - Spread to lymph nodes may be detected as firm masses in the supraclavicular area, axilla, or groin.
 - Extrathoracic metastases are common (found at autopsy in 50% to 95%) and may cause neurologic symptoms with brain metastases; pain and fracture with bone metastases; cytopenias or leukoerythroblastosis from bone marrow involvement; and liver dysfunction from metastases to the liver.
 - Paraneoplastic syndromes are common in SCLC and include endocrine syndromes (seen in 12%), such as hypercalcemia and hypophosphatemia from elevated parathyroid hormone or parathyroid-hormone related peptide; hyponatremia from secretion of antidiuretic hormone; electrolyte disturbances as seen with secretion of adrenocorticotrophic hormone; and Lambert-Eaton myasthenic syndrome (primarily proximal muscle weakness, abnormal gait, fatigue, autonomic dysfunction, paresthesias). The most common paraneoplastic syndromes in SCLC are the syndrome of inappropriate antidiuresis (15% to

40% of patients with SCLC) and Cushing syndrome (2% to 5% of patients with SCLC).⁸

- Skeletal and connective tissue syndromes including clubbing (seen in 30%, especially with non–small cell carcinoma) and hypertrophic pulmonary osteoarthropathy with pain and swelling from periostitis (1% to 10%, especially with adenocarcinoma).
- Skin nodules from lung cancer metastases may not be painful but are a poor prognostic sign (**Figures 58-1** and **58-2**).

LABORATORY TESTING

- Molecular testing for mutational profiles is becoming more common for NSCLC with the rapid development of targeted therapies. Specifically, identification of activating EGFR mutations is the best predictor for response to EGFR-tyrosine kinase inhibitors.⁹ In one multicenter study in Spain, EGFR mutations were found in 16.6% (350 of 2105) of patients and were more frequent in women (69.7%), in never smokers (66.6%), and in those with adenocarcinomas (80.9%).¹⁰

IMAGING

- For an incidental lung nodule not believed to be lung cancer, the American College of Radiology (ACR) recommends either percutaneous lung biopsy or whole-body fluorine-18-2-fluoro-2-deoxy-D-glucose-positron emission tomography (FDG-PET), the latter if the patient has lung cancer risk factors.¹¹ Follow-up imaging only is recommended for selected patients with no lung cancer risk factors.
- If a tumor is associated with mediastinal adenopathy, endoscopic/bronchoscopic mediastinal biopsy is recommended.¹¹ In one study, endobronchial ultrasound-guided transbronchial needle aspiration was found to be comparable to mediastinoscopy for mediastinal staging in patients with potentially resectable NSCLC.¹²
- CXR may be useful as baseline if not already performed and a chest CT scan should be performed; these tests may show a nodule (**Figures 58-3** and **58-4**) or diffuse lung abnormalities often confused with pneumonia (**Figures 58-5** to **58-7**).

TYPICAL DISTRIBUTION⁵

- Squamous and small cell carcinoma tend to present as central masses with endobronchial growth.
- Adeno- and large cell carcinoma tend to present as peripheral masses, frequently with pleural involvement.

BIOPSY: HISTOLOGY⁵

- SCLCs have scant cytoplasm, hyperchromatic nuclei with fine chromatin pattern, nucleoli that are indistinct, and diffuse sheets of cells.
- NSCLCs have abundant cytoplasm, pleomorphic nuclei with coarse chromatin pattern, prominent nucleoli, and glandular or squamous architecture.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of an individual with lung findings (e.g., productive cough and dyspnea) includes:

FIGURE 58-3 Chest x-ray demonstrating a 2.5-cm irregular nodule in the left upper lobe.

FIGURE 58-4 CT scan of the patient in Figure 58-3 shows a spiculated mass confirmed at surgery to be an adenocarcinoma. (From *Diagnostic Thoracic Imaging* Courtesy of Miller, W. *Diagnostic Thoracic Imaging*. New York: McGraw-Hill. 2006.)

- Chronic obstructive pulmonary disease—Most common symptoms are cough, sputum production and exertional dyspnea. Although hemoptysis may occur, imaging (chest CT is most definitive) will not show a tumor. There is an increased risk of lung cancer in these patients (Chapter 56, Chronic Obstructive Pulmonary Disease).
- Pneumonia—Symptoms include fever, chills, and pleuritic chest pain; physical findings include dullness to percussion, bronchial breathing, egophony (E to A change), and crackles with area of infiltrate (pneumonia usually confirmed on CXR; Chapter 53, Pneumonia).

Both these processes may occur in conjunction with lung cancer.

MANAGEMENT

Treatment is based on staging and cell type; both anatomic (e.g., physical location of tumor) and physiologic (e.g., patient's ability to withstand treatment) factors are considered. All patients should undergo the following:^{5,8} **SOR C**

- Complete history and physical.
- Laboratory tests—Complete blood count with differential and platelets, electrolytes, glucose, calcium, phosphorus, and renal and liver function tests.

For staging purposes for NSCLC the ACR recommends the following imaging:¹³

- CT chest scan with contrast, if there are no strong contraindications, and a FDG-PET from skull base to midthigh. Use of FDG-PET has been shown to identify more patients with mediastinal and extrathoracic disease than conventional staging.¹⁴ Although this approach spares more patients from stage-inappropriate surgery, the strategy appears to incorrectly upstage disease in some patients and, in one randomized controlled trial (RCT), did not affect overall mortality.¹⁵
- If a patient has neurologic symptoms or an adenocarcinoma larger than 3 cm or mediastinal adenopathy, an MRI of the head without and with contrast are recommended.¹¹
- In addition, for patients with non-small cell tumors who may be candidates for curative surgery or radiotherapy, obtain pulmonary function tests, coagulation tests, and possibly cardiopulmonary exercise testing.⁵

For staging of patients with SCLC, ACR recommends:¹¹

- CT chest scan with contrast, if there are no strong contraindications, FDG-PET from skull base to midthigh, MRI of the head without and with contrast, and CT scan of the abdomen (liver metastases are common at diagnosis). The use of FDG-PET scanning is controversial for patients with SCLC as most chemoradiation studies were performed prior to use of this scan.⁸

Staging for patients with lung cancer is based on the TNM classification system where T describes the size of the tumor, N describes any regional lymph node involvement, and M notes the presence or absence of distant metastases (**Box 58-1**).¹⁶ At diagnosis, approximately 15% have localized disease, 22% have regional disease (spread to regional lymph nodes), and 56% have distant metastases.²

FIGURE 58-5 Diffuse lung abnormality seen on chest x-ray best characterized as ground-glass opacity, slightly worse in the right upper lobe. Open biopsy demonstrated bronchoalveolar carcinoma. (From *Diagnostic Thoracic Imaging* Courtesy of Miller, W. *Diagnostic Thoracic Imaging*. New York. McGraw-Hill. 2006.)

FIGURE 58-6 Chest x-ray showing local area of consolidation in the left lower lobe. Worsening consolidation for the subsequent 2 months despite antibiotic treatment led to a surgical biopsy, which confirmed bronchoalveolar carcinoma. (From *Diagnostic Thoracic Imaging* Courtesy of Miller, W. *Diagnostic Thoracic Imaging*. New York. McGraw-Hill. 2006.)

NONPHARMACOLOGIC

Supportive care for the patient and family and palliative care of the patient should be provided, including adequate pain relief.

- Early palliative care was shown in one trial to improve quality of life and mood and increased median survival (11.6 months vs. 8.9 months) for patients with metastatic NSCLC compared to those receiving standard care.¹⁷
- Smoking cessation—In a metaanalysis, continued smoking was associated with a significantly increased risk of all-cause mortality and recurrence in early stage NSCLC and of all-cause mortality, development of a second primary tumor and recurrence in limited stage (all but stage IV) SCLC.¹⁸ Using life-table modeling, these investigators estimated that 5-year survival in 65-year-old patients with early stage NSCLC who quit smoking would increase from 33% (for those who continued to smoke) to 70% and for those with limited stage SCLC, from 29% (continued smokers) to 63% (quitters) (Chapter 236, Tobacco Addiction).

FIGURE 58-7 CT at the level of the bases in the patient in Figure 58-6 showing areas of ground-glass opacification in the left lower lobe and lingula. (From *Diagnostic Thoracic Imaging* Courtesy of Miller, W. *Diagnostic Thoracic Imaging*. New York. McGraw-Hill. 2006.)

BOX 58-1 TNM Staging of Lung Cancer

- Stage 0 – Carcinoma in situ (Tis N0 M0)
- Stage IA – Tumor size 2 centimeters (cm) or smaller (1a) or tumor size >2 cm but <3 cm (1b) (T1a,b N0 M0)
- Stage IB – Tumor size >3 cm but <5 cm (2a) and has any of the following: involves the main bronchus (>2 cm distal to the carina), invades visceral pleura, or associated with atelectasis or obstructive pneumonitis extending to the hilar region (T2a N0 M0)
- Stage IIA – Tumor size >5 cm but <7 cm (2b) (T2b N0 M0, T1a,b N1 M0, T2a N1 M0)
- Stage IIB – Tumor size >5 cm but <7 cm (2b) or tumor size >7 cm or directly invades the chest wall, diaphragm, phrenic nerve, mediastinal pleura, parietal pericardium; or tumour in the main bronchus <2 cm distal to the carina but without carina involvement; or associated atelectasis or obstructive pneumonitis of the entire lung or separate tumour nodule(s) in the same lobe as the primary (T3) (T2b N1 M0, T3 N0 M0)
- Stage IIIA – Any size tumor including a tumor that invades the mediastinum, heart, great vessels, trachea, recurrent laryngeal nerve, oesophagus, vertebral body, carina or separate tumor in a different ipsilateral lobe to that of the primary (T4) (T1a,b or T2a,b N2 M0, T3 N1 or 2 M0, T4 N0 or 1 M0)
- Stage IIIB – T4 N2 M0, any T N3 M0
- Stage IV – tumor has spread to distant sites (Any T any N M1)

T, Tumor (size and extent); N, regional lymph nodes (N0 no regional lymph node metastasis, N1 metastasis in ipsilateral peribronchial and/or ipsilateral hilar lymph nodes and intrapulmonary nodes, including involvement by direct extension, N2 metastasis in ipsilateral mediastinal and/or subcarinal lymph node[s], N3 metastasis in contralateral mediastinal, contralateral hilar, ipsilateral or contralateral scalene, or supraclavicular lymph node[s]); M, metastases (M0 no distant metastasis, M1 distant metastasis).

MEDICATIONS

- Pain medication should be provided as needed (Chapter 5, End of Life). Opioids, such as codeine or morphine, may reduce cough.
- Adjuvant chemotherapy in patients with NSCLC, with or without postoperative radiotherapy, increases 5-year survival by approximately 4% to 5%.^{8,19}
- Preoperative chemotherapy in patients with NSCLC increases survival by approximately 6% (absolute benefit) at 5 years.²⁰ Advantages of preoperative chemotherapy include early start on potential micrometastases and higher adherence to therapy.⁸
- Maintenance therapy with either cytotoxic agents or tyrosine kinase inhibitor agents (or switch therapy) can be considered as it appears to increase overall survival for patients with nonprogressive NSCLC.²¹
- Management of patients with SCLC includes combination, platinum-based chemotherapy (see Surgery and Radiation, management of very limited SCLC.).^{5,22} **SOR A** Targeted therapies have not proved beneficial for patients with SCLC.²²

COMPLEMENTARY AND ALTERNATIVE THERAPY

- In a small RCT of patients with NSCLC on chemotherapy, nutritional intervention with 2.2 g of fish oil per day provided a benefit on maintenance of weight and muscle mass over standard care.²³ Fish oil also increased the response to chemotherapy in those with advanced NSCLC, and may provide a survival benefit (trend).²⁴

SURGERY AND RADIATION

Management of patients with NSCLC includes the following:

- Localized stages I and II—Pulmonary resection. **SOR A**
Evidence is conflicting about whether video-assisted thoracoscopic surgery offers advantages over standard lobectomy; either technique can be used.^{8,25,26}
- In patients undergoing resection, intraoperative systematic mediastinal lymph node sampling or dissection is recommended for accurate staging.²⁵ Although data are limited, a Cochrane review concluded that resection combined with complete mediastinal lymph node dissection is associated with a modest survival improvement compared with resection combined with systematic sampling of mediastinal nodes in patients with stages I to IIIA NSCLC.²⁷
- For patients with stage I disease who are not surgical candidates, external-beam radiotherapy is recommended²⁸; stereotactic body radiation therapy or percutaneous ablation can be considered as a treatment option.^{25,26} **SOR B**
- Adjuvant chemotherapy is recommended for patients with stage II disease.^{25,29}
- Stage IIIA and favorable age, cardiovascular function, and anatomy—Possible surgery and/or concurrent chemo/radiation therapy.
- Stage IIIB—Concurrent chemo/radiation therapy.²⁵
- Stage IV—Options include radiation therapy to symptomatic local sites, chemotherapy or molecular targeted agents, chest tube for malignant effusion, and consideration of resection of primary or isolated brain or adrenal metastases.^{5,25} A Cochrane review

concluded that chemotherapy improves overall survival in patients with advanced NSCLC (absolute improvement in survival of 9% at 12 months [20% to 29%] or absolute increase in median survival of 1.5 months [from 4.5 months to 6 months]).³⁰

- Curative radiotherapy should be considered for patients with good performance status and inoperable stages I to III disease.²⁵

Management of patients with very limited (stage I) SCLC is surgical resection and adjuvant combined cisplatin-based chemotherapy, possibly with prophylactic cranial irradiation.²²

- Other patients with limited-stage SCLC (stages II to III) should be offered thoracic irradiation concurrently with the first or second cycle of chemotherapy or following completion of chemotherapy if there has been at least a good partial response within the thorax.^{5,22} Prophylactic cranial irradiation should be considered if nonprogressive after induction treatment.²²
- For patients with extensive disease (stage IV), limited data support prolonged survival (added 63 to 84 days) using chemotherapy.³¹ Supportive care plus palliative thoracic irradiation should be considered following chemotherapy (combination etoposide and cisplatin for non-Asian patients and irinotecan and cisplatin for Asian patients).²²
- For patients who are not candidates for chemotherapy, palliative radiotherapy should be considered.²² Palliative radiotherapy is associated with a modest increase in survival (5% at 1 year) in patients with better performance status who are given higher-dose radiotherapy.³² Other targeted therapies, based on molecular testing of tumor mutational profiles (e.g., erlotinib for mutant EGFR) should be considered.
- External-beam radiotherapy could also be considered for the relief of breathlessness, cough, hemoptysis, or chest pain.⁵

PREVENTION

- Avoid smoking/smoking exposure or quit, if already smoking (Chapter 236, Tobacco Addiction). Avoid workplace and home exposures (listed in risk factors).
- Daily aspirin appears to protect against lung adenocarcinoma.³³
- Routine screening for lung cancer is not currently recommended; the U.S. Preventive Services Task Force concluded that there is insufficient evidence to support screening with any modality.³⁴ Results of the Prostate, Lung, Colorectal, and Ovarian (PLCO) Cancer Screening Trial (N = 154,901) demonstrated no benefit of annual CXR screening on reducing lung cancer mortality compared with usual care.³⁵
- However, the National Lung Screening Trial (N = 53,454 patients at high-risk for lung cancer) reported lower mortality from lung cancer after three annual screenings for patients randomized to low-dose CT versus single-view posteroanterior chest radiography (247 deaths from lung cancer per 100,000 person-years and 309 deaths per 100,000 person-years, respectively).³⁶ There was also reduced all-cause mortality in this group by 6.7%. As the risk of false positives with low-dose CT is high (33% after two screenings),³⁷ and there is potential for radiation-induced cancer, it is not clear that routine screening for high-risk patients should be conducted.

PROGNOSIS

- Perioperative mortality from a large database of over 18,000 lung cancer resections performed at 111 participating centers was 2.2% and composite morbidity and mortality occurred in 8.6%.³⁸ Predictive factors of mortality included pneumonectomy, bilobectomy, performance status, induction chemoradiation, steroids, age, and renal dysfunction among other factors.
- Adverse prognostic factors for NSCLC include presence of pulmonary symptoms, large tumor size (>3 cm), nonsquamous histology, metastases to multiple lymph nodes within a TNM-defined nodal station, and vascular invasion.⁴
- The overall 5-year relative survival from lung cancer (SEER data 2001-2007) was 15.6%. Five-year relative survival by race and sex was 18.3% for white women, 14.5% for black women, 13.7% for white men, and 11.6% for black men.²
- Five-year survival decreases by stage at diagnosis ranging from 52.2% for localized disease to 3.6% for those with distant metastases.² Estimates for 5-year survival by stage are: Stage IA 73%, Stage IB 65%, Stage IIA 46%, Stage IIB 36%, Stage IIIA 24%, Stage IIIB 9%, and Stage IV 13%.¹⁶
- For SCLC, median survival for patients with limited-stage disease is approximately 15 to 20 months (20% to 40% survive to 2 years). For those with extensive-stage SCLC disease, median survival is approximately 8 to 13 months with 2-year survival of 5%.⁸
- Following lung cancer resection, there is a 1% to 2% risk per patient per year that a second lung cancer will occur.⁵ One author reported higher risks of second tumors in long-term survivors, including rates of 10% for second lung cancers and 20% for all second cancers.³⁹ For patients with SCLC, second primary tumors are reported in 2% to 10% of patients per year.²²

FOLLOW-UP

Surveillance for the recognition of a recurrence of the original lung cancer and/or the development of a metachronous tumor should be coordinated through a multidisciplinary team approach.

- This team should develop a lifelong surveillance plan appropriate for the individual circumstances of each patient immediately following initial curative-intent therapy.⁵ **SOR** 
- In patients following curative-intent therapy for lung cancer, the use of blood tests, FDG-PET scanning, sputum cytology, tumor markers, and fluorescence bronchoscopy is not currently recommended for surveillance.²

PATIENT EDUCATION

- Smoking cessation, never initiating smoking, and avoidance of occupational and environmental exposure to carcinogenic substances are recommended to reduce the risk of recurrence or a second primary in curatively treated patients. In patients with metastatic disease, although smoking cessation has little effect on overall prognosis, it may improve respiratory symptoms.

- Information about local hospice services and support groups should be provided. The Lung Cancer Alliance website, listed in “Patient Resources” below, can be used to find support groups.

PART 9

GASTROINTESTINAL

Strength of Recommendation (SOR)	Definition
A	Recommendation based on consistent and good-quality patient-oriented evidence.*
B	Recommendation based on inconsistent or limited-quality patient-oriented evidence.*
C	Recommendation based on consensus, usual practice, opinion, disease-oriented evidence, or case series for studies of diagnosis, treatment, prevention, or screening.*

*See Appendix A on pages 1447–1450 for further information.

59 PEPTIC ULCER DISEASE

Hend Azhary, MD
Mindy A. Smith, MD, MS

PATIENT STORY

A 41-year-old man presents with a 4-month history of epigastric pain. The pain is dull, achy, and intermittent; there is no radiation of the pain and it has not changed in character since it began. Coffee intake seems to exacerbate the symptoms while eating or drinking milk helps. Infrequently, he is awakened at night from the pain. He reports no weight loss, vomiting, melena, or hematochezia. On examination, there is mild epigastric tenderness with no rebound or guarding. The remainder of the examination is unremarkable. A stool antigen test is positive for *Helicobacter pylori*, and the patient is treated for peptic ulcer disease with eradication therapy.

INTRODUCTION

Peptic ulcer disease (PUD) is a disease of the gastrointestinal (GI) tract characterized by a break in the mucosal lining of the stomach or duodenum secondary to pepsin and gastric acid secretion, this damage is greater than 5 mm in size and with a depth reaching the submucosal layer.¹

EPIDEMIOLOGY

- PUD is a common disorder affecting approximately 4.5 million people annually in the United States. It encompasses both gastric and duodenal ulcers (**Figures 59-1** and **59-2**).²
- One-year point prevalence is 1.8%, and the lifetime prevalence is 10% in the United States.²
- Prevalence is similar in both sexes, with increased incidence with age.¹ Duodenal ulcers most commonly occur in patients between the ages of 30 and 55 years, whereas gastric ulcers are more common in patients between the ages of 55 and 70 years.²
- PUD incidence in *H. pylori*-infected individuals is approximately 1% per year (6- to 10-fold higher than uninfected subjects).¹
- Physician office visit and hospitalization for PUD have decreased in the last few decades.¹
- The current U.S. annual direct and indirect health care costs of PUD are estimated at approximately \$10 billion. However, the incidence of peptic ulcers keeps declining, possibly as a result of the increasing use of proton pump inhibitors and eradication of *H. pylori* infection.³

ETIOLOGY AND PATHOPHYSIOLOGY

- Causes of PUD include:
 - NSAIDs, chronic *H. pylori* infection, and acid hypersecretory states such as Zollinger-Ellison syndrome.²

FIGURE 59-1 Endoscopic pictures of a gastric ulcer. Plates 1 and 2 show erosions. Note that the bleeding is from biopsy. Plates 3 and 4 show a large crater with evidence of recent bleeding. Both are consistent with severe ulcer disease. (Courtesy of Michael Harper, MD.)

FIGURE 59-2 Endoscopic view of a pyloric ulcer and an erosion of the mucosa. The ulcer and erosion are benign peptic ulcer disease and not malignant. (Courtesy of Marvin Derezin, MD.)

- Uncommon causes include *Cytomegalovirus* (especially in transplantation recipients), systemic mastocytosis, Crohn disease, lymphoma, and medications (e.g., alendronate).²
- Up to 10% of ulcers are idiopathic.²
- Infection with *H. pylori*, a short, spiral-shaped, microaerophilic Gram-negative bacillus, is the leading cause of PUD. It is associated with up to 70% to 80% of duodenal ulcers.²
- *H. pylori* colonize the deep layers of the gel that coats the mucosa and disrupt its protective properties causing release of certain enzymes and toxins. These make the underlying tissues more vulnerable to damage by digestive juices and thus cause injury to the stomach (**Figures 59-1 to 59-3**) and duodenum cells.¹
- NSAIDs are the second most common cause of PUD and account for many *H. pylori*-negative cases.
- NSAIDs and aspirin inhibit mucosal cyclooxygenase activity reducing the level of mucosal prostaglandin causing defects in the protective mucous layer.
- There is a 10% to 20% prevalence of gastric ulcers and a 2% to 5% prevalence of duodenal ulcers in long-term NSAID users.² The annual risk of a life-threatening ulcer-related complication is 1% to 4% in long-term NSAID users, with older patients having the highest risk.⁷

RISK FACTORS

- Severe physiologic stress—Burns, central nervous system trauma, surgery, and severe medical illness increase the risk for secondary (stress) ulceration.⁴
- Smoking—Evidence that tobacco use is a risk factor for duodenal ulcers is not conclusive, with several studies producing contradictory findings. However, smoking in the setting of *H. pylori* infection may increase the risk of relapse of PUD.⁵
- Alcohol use—Ethanol is known to cause gastric mucosal irritation and nonspecific gastritis. Evidence that consumption of alcohol is a risk factor for duodenal ulcer is inconclusive.⁵
- Medications—Corticosteroids alone do not increase the risk for PUD; however, they can potentiate ulcer risk in patients who use NSAIDs concurrently.⁴

DIAGNOSIS

CLINICAL FEATURES

- Epigastric pain (dyspepsia), the hallmark of PUD, is present in 80% to 90% of patients; however, this symptom is not sensitive or specific enough to serve as a reliable diagnostic criterion for PUD. Pain is typically described as gnawing or burning, occurring 1 to 3 hours after meals and relieved by food or antacids. It can occur at night, and sometimes radiates to the back.² Less than 25% of patients with dyspepsia have ulcer disease at endoscopy.⁴
- Other dyspeptic symptoms including belching, bloating, and distention are common but also not specific features of PUD as they are commonly encountered in many other conditions.

FIGURE 59-3 Stomach ulcer in a patient with a hiatal hernia. (Courtesy of Michael Harper, MD.)

- Additional symptoms include fatty food intolerance, heartburn, and chest discomfort.
- Nausea and anorexia may occur with gastric ulcers.
- Significant vomiting and weight loss are unusual with uncomplicated ulcer disease and suggest gastric outlet obstruction or gastric malignancy.²
- Twenty percent of patients with ulcer complications such as bleeding and nearly 61% of patients with NSAID-related ulcer complications have no antecedent symptoms.
- Rare and nonspecific physical findings include:
 - Epigastric tenderness.
 - Heme-positive stool.
 - Hematemesis or melena in cases of GI bleeding.

TYPICAL DISTRIBUTION

- Duodenal ulcers occur most often in the first portion of the duodenum (>95%), with approximately 90% of ulcers located within 3 cm of the pylorus.¹
- Benign gastric ulcers are located most commonly in the antrum (60%) and at the junction of the antrum and body on the lesser curvature (25%) (**Figure 59-3**).¹

LABORATORY STUDIES

- In most patients with uncomplicated PUD, routine laboratory tests are not helpful.⁴
- Noninvasive tests include serum *H. pylori* antibody detection, fecal antigen tests, and urea breath tests; the latter two, if positive, indicate active disease.⁶
- Serum enzyme-linked immunosorbent assay (ELISA) is the least accurate test and is useful only for diagnosing the initial infection.
- The stool antigen test is less convenient but is highly accurate and also can be used to confirm *H. pylori* eradication, as can the urea breath test.⁶
- Obtaining a serum gastrin may be useful in patients with recurrent, refractory, or complicated PUD and in patients with a family history of PUD to screen for Zollinger-Ellison syndrome.¹

IMAGING

- Upper endoscopy is the procedure of choice for the diagnosis of duodenal and gastric ulcers (**Figures 59-1 to 59-3**).²
- Endoscopy provides better diagnostic accuracy than barium radiography and affords the ability to biopsy for the presence of malignancy and *H. pylori* infection. Endoscopy is usually reserved for the following situations:
 - Patients with red flag signs (e.g., bleeding, dysphagia, severe pain, abdominal mass, recurrent vomiting, weight loss) or age older than 55 years.
 - Patients who fail initial therapy.
 - Patients whose symptoms recur after appropriate therapy.
- Duodenal ulcers are virtually never malignant and do not require biopsy.²
- Gastric ulcers should be biopsied because 3% to 5% of benign-appearing gastric ulcers prove to be malignant.²

- Barium upper gastrointestinal (UGI) series is an acceptable alternative to endoscopy but is not as sensitive for the diagnosis of small ulcers (<0.5 cm) and does not allow for biopsy with gastric ulcer.⁶
- Patient's testing positive for PUD should undergo noninvasive testing for *H. pylori*.
- UGI series has limited accuracy in distinguishing benign from malignant gastric ulcers; therefore, all patients diagnosed this way should be reevaluated with endoscopy after 8 to 12 weeks of therapy.

DIFFERENTIAL DIAGNOSIS

Disease processes that may present with “ulcer-like” symptoms include:

- Nonulcer or functional dyspepsia (FD)—The most common diagnosis among patients seen for upper abdominal discomfort; it is a diagnosis of exclusion. Dyspepsia has been reported to occur in up to 30% of the U.S. population.
- Gastroesophageal reflux—Classic symptoms are heartburn (i.e., substernal pain that may be associated with acid regurgitation or a sour taste) aggravated by bending forward or lying down, especially after a large meal. Endoscopy is considered if symptoms fail to respond to treatment (e.g., histamine-2-receptor agonist, proton pump inhibitor [PPI]) or red flag signs and symptoms occur.
- Gastric cancer—Most patients do not become symptomatic until late in the disease; symptoms include upper abdominal pain, postprandial fullness, anorexia and mild nausea, vomiting (especially with pyloric tumors), weight loss and a palpable mass. Endoscopic biopsy is used to make this diagnosis (see Chapter 60, Gastric Cancer).
- Biliary colic is characterized by discrete, intermittent episodes of pain that should not be confused with other causes of dyspepsia.
- Gastroduodenal Crohn disease—Symptoms include epigastric pain, nausea, and vomiting. On endoscopy, patients often have *H. pylori*-negative gastritis and may develop gastric outlet obstruction. Extraintestinal manifestations include erythema nodosum, peripheral arthritis, conjunctivitis, uveitis, and episcleritis. Endoscopy shows an inflammatory process with skip lesions, fistulas, aphthous ulcerations, and rectal sparing. Small bowel involvement is seen on imaging with longitudinal and transverse ulceration (cobblestoning) in addition to segmental colitis and frequent stricture (see Chapter 65, Inflammatory Bowel Disease).

MANAGEMENT

- The approach to patients with dyspepsia includes performing endoscopy for patients with red flag symptoms or who are older than age 55 years. For patients who have an ulcer identified on endoscopy, eradication of *H. pylori* is attempted (as below) and a PPI is continued for 4 to 8 weeks. For those without an ulcer on endoscopy, treatment with a PPI or H₂ blocker is provided.⁷
- For patients without red flag findings, testing and treating for *H. pylori*; counseling to avoid smoking, alcohol, and NSAIDs; and

appropriate use of antisecretory therapy for 4 weeks will be successful in the majority of patients.⁷

- The goals of treatment of active *H. pylori*-associated ulcers are to relieve dyspeptic symptoms, to promote ulcer healing, and to eradicate *H. pylori* infection. Eradication of *H. pylori* is better than ulcer-healing drug therapy for duodenal ulcer healing⁸ and greatly reduces the incidence of ulcer recurrence from 67% to 6% in patients with duodenal ulcers and from 59% to 4% in patients with gastric ulcers.⁷
- The worldwide empiric use of traditional triple therapy with PPI, clarithromycin, and amoxicillin no longer provides an acceptable cure rate (cure rate below 80%) because of the increasing prevalence of clarithromycin resistance.⁹
- Four drug combinations currently provide the best results and consist of two general combinations: (a) a PPI, amoxicillin, clarithromycin, metronidazole/tinidazole given either sequentially or concomitantly, or (b) a PPI, a bismuth, tetracycline HCL, and metronidazole/tinidazole. ⁹ **SOR A**
- A PPI, levofloxacin, and amoxicillin for 10 days appears to be more effective and better tolerated than a PPI, bismuth, tetracycline, and metronidazole in patients with persistent *H. pylori* infection but requires validation in North America.⁶
- The European Helicobacter Study Group consensus guideline states that triple therapy (PPI-clarithromycin-amoxicillin/metronidazole) or Bismuth quadruple therapy remain first-line treatment in areas with low clarithromycin resistance. For areas with high clarithromycin resistance (>20%), Bismuth or non-Bismuth quadruple therapy are preferred.¹⁰
- Treat NSAID-induced ulcers with cessation of NSAIDs, if possible, and an appropriate course of standard ulcer therapy with a H₂-receptor antagonist or a PPI. If NSAIDs are continued, prescribe a PPI. **SOR A**
- *H. pylori*-negative ulcers that are not caused by NSAIDs can be treated with appropriate antisecretory therapy, either H₂-receptor antagonist or PPI. **SOR A**
- For patients with bleeding peptic ulcers, high-dose PPIs do not reduce rates of rebleeding, surgical intervention, or mortality after endoscopic treatment compared with non-high-dose PPIs.¹¹

PREVENTION

- In a large randomized controlled trial (RCT) (N = 2426) of PUD prevention in patients taking low-dose acetylsalicylic acid who were at risk for ulcer development (e.g., prior ulcer, GI symptoms and erosions, age older than 65 years), esomeprazole 40 mg or 20 mg reduced the rate of endoscopically confirmed peptic ulcer development (1.5% and 1.1%, respectively) versus placebo (7.4%).¹²
- Authors of a metaanalysis found the use of prophylactic H₂ blockers to prevent stress ulcers was not necessary in patients receiving enteral nutrition and that such therapy was associated with pneumonia and higher risk of hospital mortality.¹³ In another metaanalysis, PPIs were similar to H₂-receptor antagonists in terms of stress-related UGI bleeding prophylaxis, pneumonia, and mortality among patients admitted to intensive care units.¹⁴

PROGNOSIS

- Hospitalization rate is approximately 30 per 100,000 cases.⁴
- Mortality rate is approximately 1 per 100,000 cases.⁴
- When the underlying cause is addressed the prognosis is excellent.
- With the eradication of *H. pylori* infection there has been decrease in the ulcer recurrence rate from 60% to 90% to approximately 10% to 20% with the regard to NSAID-related ulcers.⁴
- The incidence of perforation is approximately 0.3% per patient year, and the incidence of obstruction is approximately 0.1% per patient year.⁴

FOLLOW-UP

- Endoscopy is required to document healing of gastric ulcers and to rule out gastric cancer; this is performed 6 to 8 weeks after the initial diagnosis.
- Confirmation of *H. pylori* eradication in patients with uncomplicated ulcers is not necessary.
- Confirmation of healing with endoscopy is required in all patients with ulcer complicated by bleeding, perforation, or obstruction.
- For patients without initial endoscopy who have persistent symptoms following initial treatment, the PPI or H₂ blocker can be continued for another 4 to 8 weeks.⁷ If there is inadequate response to therapy, endoscopy and evaluation for hypersecretory states should be considered.

PATIENT EDUCATION

- Patients with PUD should be encouraged to eat balanced meals at regular intervals, avoid heavy alcohol use, and avoid smoking (which has been shown to retard the rate of ulcer healing and increase the frequency of recurrences); stress reduction counseling might be helpful in individual cases.

60 GASTRIC CANCER

Mindy A. Smith, MD, MS

PATIENT STORY

A 72-year-old Japanese immigrant was brought in by his family with complaints of difficulty in eating, vague abdominal pain, and weight loss. Endoscopy and biopsy confirmed gastric adenocarcinoma (**Figure 60-1**). Liver metastases were found on abdominal CT. The family and the patient chose only comfort measures and the patient died 6 months later.

INTRODUCTION

Gastric cancer is a malignant neoplasm of the stomach, usually adenocarcinoma.

EPIDEMIOLOGY

- Based on Surveillance Epidemiology and End Results (SEER) data, an estimated 12,730 men and 8270 women will be diagnosed with gastric cancer, and 10,570 men and women will die of this cancer in 2012 (2010).¹ The median age at diagnosis is 70 years and median age at death from gastric cancer is 73 years.¹
- Stomach cancer occurs in 10.8 per 100,000 men and 5.4 per 100,000 women in a year. In 2008, the United States prevalence was 37,739 men and 28,271 women, with a lifetime risk of 0.88%.¹
- High rates of stomach cancer occur in Japan, China, Chile, and Ireland.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Eighty-five percent of stomach cancers are adenocarcinomas with 15% lymphomas and GI stromal tumors.² Adenocarcinoma is further divided into two types:
 - Diffuse type—Characterized by absent cell cohesion, these tumors affect younger individuals infiltrating and thickening the stomach wall; the prognosis is poor. Several susceptibility genes have been identified for this type of cancer.³
 - Intestinal type—Characterized by adhesive cells forming tubular structures, these tumors frequently ulcerate.
- Tumor grade can be well (4.1%), moderate (23.1%), or poorly differentiated (54.9%), or undifferentiated (2.9%) (SEER data from 1988–2001; unknown type accounted for 15%).⁴
- Most tumors are thought to arise from ingestion of nitrates that are converted by bacteria to carcinogens. Exogenous and endogenous factors (see “Risk Factors” below) contribute to this process.²
 - Exogenous sources of nitrates—Sources include foods that are dried, smoked, and salted. *Helicobacter pylori* infection may

FIGURE 60-1 Endoscopy showing a raised and irregular mass in the antrum of the stomach deforming the pylorus. It fills the distal one-half of the antrum. The lesion was hard when probed with biopsy forceps. Biopsy indicated adenocarcinoma. (Courtesy of Michael Harper, MD.)

contribute to carcinogenicity by creating gastritis, loss of acidity, and bacterial growth.

- Oncogenic pathways identified in most gastric cancers are the proliferation/stem cell, nuclear factor- κ B, and Wnt/ β -catenin; interactions between them appear to influence disease behavior and patient survival.⁵
- Gastric tumors are classified for staging using the T (tumor) N (nodal involvement) M (metastases) system. Two important prognostic factors are depth of invasion through the gastric wall (less than T2 [tumor invades muscularis propria]) and presence or absence of regional lymph node involvement (N0). Changes made to the classification system in the seventh edition of the American Joint Commission's *Cancer Staging Manual* for gastric cancer⁶ demonstrate better survival discrimination.⁷
- Gastric cancer spreads in multiple ways:²
 - Local extension through the gastric wall to the perigastric tissues, omenta, pancreas, colon, or liver.
 - Lymphatic drainage through numerous pathways leads to multiple nodal group involvement (e.g., intraabdominal, supraclavicular) or seeding of peritoneal surfaces with metastatic nodules occurring on the ovary, periumbilical region, or peritoneal cul-de-sac.
 - Hematogenous spread is also common with liver metastases.

RISK FACTORS

- Previous gastric surgery—As a result of alteration of the normal pH or with biopsy showing high-grade dysplasia.^{2,8}
- Other endogenous risk factors—Atrophic gastritis (including postsurgical vagotomized patients) and pernicious anemia are conditions that favor the growth of nitrate-converting bacteria. In addition, intestinal-type cells that develop metaplasia and possibly atypia can replace the gastric mucosa in these patients. Genetic polymorphisms (e.g., interleukin-1B-511, interleukin-1RN, and tumor necrosis factor- α) also appear to play a role. Familial adenomatous polyposis and hereditary nonpolyposis colorectal cancer are also risk factors.⁸
- Individuals infected with certain *H. pylori* bacteria (cytotoxin-associated gene A) are at increased risk of gastric adenocarcinoma (especially noncardia) and gastric mucosa-associated lymphoid tissue (MALT) lymphoma.⁹
- Additional risk factors—Smoking, low socioeconomic class, lower educational level, exposure to certain pesticides (e.g., those who work in the citrus fruit industry in fields treated with 2,4-dichlorophenoxyacetic acid [2,4-D], chlordane, propargite, and triflurin¹⁰), radiation exposure, and blood type A.

DIAGNOSIS

CLINICAL FEATURES²

- Asymptomatic, if superficial and/or early.
- Upper abdominal pain that ranges from vague to severe.
- Postprandial fullness.
- Anorexia and mild nausea are common.

- Nausea and vomiting occur with pyloric tumors.
- Late symptoms include weight loss and a palpable mass (regional extension).
- Late complications include peritoneal and pleural effusions; obstruction of the gastric outlet; bleeding from esophageal varices or postsurgical site; and jaundice.¹¹
- Physical signs are also late features and include:¹¹
 - Palpable enlarged stomach with succussion splash (splashing sound on shaking, indicative of the presence of fluid and air in a body cavity).
 - Primary mass (rare).
 - Enlarged liver.
 - Enlarged, firm to hard, lymph nodes (i.e., left supraclavicular [Virchow]), periumbilical region (Sister Mary Joseph node), and peritoneal cul-de-sac (Blumer shelf; palpable on vaginal or rectal examination).

TYPICAL DISTRIBUTION

- Based on SEER data from 1988–2001, gastric tumors occur most often in the cardia (25.5%) and gastric antrum (20.7%), followed by the lesser curvature (9.9%), body (7.4%) and greater curvature (4.3%), and fundus (4.1%). Overlapping lesions were reported in 9.8% and no specific information was available in 15.2%.⁴
- Rates of noncardia gastric cancer appear to be decreasing.⁹

IMAGING AND ENDOSCOPY

- Diagnosis can be made on endoscopy (**Figures 60-1** and **60-2**) with biopsy of suspicious lesions. Confocal laser endomicroscopy may improve detection of early lesions.¹²
- Urgent referral for endoscopy (within 2 weeks) is recommended for patients with dyspepsia who also have GI bleeding, dysphagia, progressive unexplained weight loss, persistent vomiting, iron-deficiency anemia, epigastric mass, family history of gastric cancer (onset <50 years), or whose dyspepsia is persistent and they are older than age 55 years.¹³ **SOR C**
- Double-contrast radiography is an alternative to endoscopy and can detect large primary tumors but distinguishing benign from malignant disease is difficult.²
- Although endoscopy is not necessary when radiography demonstrates a benign-appearing ulcer with evidence of complete healing at 6 weeks, some authors recommend routine endoscopy, biopsy, and brush cytology when any gastric ulcer is identified.²
- Some gastric polyps (adenomas, hyperplastic) have malignant potential and should be removed.¹⁴
- Work-up for metastases includes:¹⁵ **SOR C**
 - Chest radiograph.
 - CT scan or MRI of the abdomen and pelvis.
- Endoscopic sonography is useful as a staging tool when the CT scan fails to find evidence of locally advanced or metastatic disease.²

LABORATORY STUDIES

- A hemoglobin or hematocrit can identify anemia, present in approximately 30% of patients.¹¹

FIGURE 60-2 Endoscopy showing a deep ulcer with yellow-brown exudate in center of mass, consistent with cancer. Pathology confirmed a high-grade, diffuse, large B-cell lymphoma of the stomach. (Courtesy of Michael Harper, MD.)

- Electrolyte panels and liver function tests can assist in assessing the patient's clinical state and any liver involvement.¹¹
- Carcinoembryonic antigen (CEA) is increased in about half of cases.¹¹

DIFFERENTIAL DIAGNOSIS

- Peptic ulcer—Typical symptoms include epigastric pain (described as a gnawing or burning), occurring 1 to 3 hours after meals and relieved by food or antacids. Patients may also have nausea and vomiting, bloating, abdominal distention, and anorexia. Endoscopy confirms diagnosis (see Chapter 59, Peptic Ulcer Disease).
- Nonulcer dyspepsia—Includes gastroesophageal reflux disease and functional dyspepsia. Classic symptoms of gastroesophageal reflux disease are heartburn (i.e., substernal pain that may be associated with acid regurgitation or a sour taste) aggravated by bending forward or lying down, especially after a large meal; individual symptoms, however, do not help to distinguish these patients from those with peptic ulcer disease. Endoscopy is considered if symptoms fail to respond to treatment (e.g., histamine-2 receptor agonist, proton pump inhibitor) or red flag signs/symptoms occur (e.g., bleeding, dysphagia, severe pain, weight loss).
- Chronic gastritis—Includes autoimmune (body-predominant) and *H. pylori*-related (antral-predominant) types; mucosal inflammation (primarily lymphocytes) may progress to atrophy and metaplasia. Abdominal pain and dyspepsia are common symptoms and patients may have pernicious anemia.
- Esophagitis—May be mechanical or infectious (primarily viral and fungal). Symptoms include heartburn (retrosternal wave-like pain that may radiate to the neck or jaw) and painful swallowing (odynophagia); regurgitation of sour or bitter tasting material may occur with obstruction. Barium swallow or esophagoscopy can be used to establish the diagnosis.
- Esophageal cancer—Relatively uncommon malignancy of two cell types: squamous cell cancers (largely related to smoking, excessive alcohol consumption, and other agents causing mucosal trauma) and adenocarcinomas (usually arising in the distal esophagus related to reflux disease). Symptoms include progressive dysphagia and weight loss; the diagnosis is confirmed on esophagoscopy and biopsy.

MANAGEMENT

- Patients may be best managed by an experienced multidisciplinary team.¹⁶ Based on SEER data from 1988–2001, only 20% of tumors had not spread beyond the stomach, one third had spread to adjacent structures and lymph nodes and another third had distant metastases.⁴

PHARMACOLOGIC

- Chemotherapy using 5-fluorouracil (FU) and doxorubicin with or without cisplatin or mitomycin C is somewhat helpful (partial response in 30% to 50%).² The European Organization for

Research and Treatment of Cancer (EORTC)-Gastrointestinal Cancer Group notes improved outcomes for resectable gastric cancer using a strategy of perioperative (pre- and postoperative) chemotherapy or postoperative chemoradiotherapy.¹⁶ **SOR A**

- In a metaanalysis, three-drug regimens containing FU, an anthracycline, and cisplatin administered as adjunct therapy appeared to have the best survival rates,¹⁷ and another metaanalysis confirmed that postoperative adjuvant chemotherapy based on FU regimens was associated with reduced risk of death in gastric cancer in patients with resectable cancer compared with surgery alone (hazard ratio [HR] 0.82; 95% CI 0.76 to 0.90) with an absolute 5-year survival benefit of 5.7%.¹⁸ **SOR C**
- EORTC-Gastrointestinal Cancer Group found no chemotherapy combination was an accepted gold standard and that in the treatment of unresectable, locally advanced or metastatic gastric or gastroesophageal junction adenocarcinoma, response rates were poor.¹⁶

REFERRAL FOR SURGERY OR PROCEDURES

- Complete resection including adjacent lymph nodes is recommended.³ For resectable gastric adenocarcinoma, EORTC-Gastrointestinal Cancer Group recommends free-margin surgery with at least D1 resection (perigastric lymph nodes) combined to removal of a minimum of 15 lymph nodes.¹⁶
- In a metaanalysis of six trials comparing D1 with D2 (extended lymph node dissection—hepatic, left gastric, celiac, and splenic arteries, as well as those in the splenic hilum) gastrectomy for patients with resectable gastric cancer, postoperative morbidity and 30-day mortality rate were higher in the D2 group; 5-year survival was similar.¹⁹
- In a metaanalysis, laparoscopy-assisted distal gastrectomy compared to conventional distal gastrectomy was associated with lower morbidity, less pain, faster bowel function recovery, and shorter hospital stay; anastomotic and wound complications and mortality rates were similar.²⁰
- Radiation is useful for palliation for pain.

PREVENTION

- Aspirin use reduces the risk of GI cancers (20-year cancer death HR 0.65; 95% CI 0.54, 0.78); the latent period before an effect on death was seen for stomach cancer was more than 5 years.²¹
- Adherence to a relative Mediterranean diet is associated with a reduced risk of gastric cancer (HR 0.67; 95% CI 0.47, 0.94).²²
- Limited data are available regarding prevention of gastric cancer, but in a population of poorly nourished Chinese subjects, combined supplementation with beta-carotene, α -tocopherol, and selenium reduced the incidence of and mortality rate from gastric cancer and the overall mortality rate from cancer by 13% to 21%.²³
- In a metaanalysis, consumption of large amounts of allium vegetables (onions, garlic, shallots, leeks, chives) was associated with a reduced risk of gastric cancer (odds ratio [OR] 0.54; 95% CI 0.43 to 0.65).²⁴

- Despite limited data, a metaanalysis of six studies conducted primarily in Asia found a reduced gastric cancer risk (0.6% absolute risk reduction) with eradication of *H. pylori* infection.²⁵
- Screening for gastric cancer in Japan has led to a greater number of cases of gastric cancer being detected in an early stage.

PROGNOSIS

- Surgical morbidity (e.g., anastomotic leaks, infection) occurs in approximately 25% of patients and operative mortality is approximately 3%.²⁶
- Overall 5-year relative survival based on SEER 2001–2007 data was 26.3%. Five-year relative survival by race and gender was: 23.2% for white men; 27.5% for white women; 22.5% for black men; 29.4% for black women.¹
- Five-year relative survival for localized disease is 61.5%, for spread to regional nodes is 27.8%, and for metastatic disease is 3%.¹
- Median survival for grade of tumor decreases from well-differentiated tumors (22.6 months) to undifferentiated (7.6 months).⁴

FOLLOW-UP

- Recurrences occur in the first 8 years.
- Follow-up varies from evaluation based on clinical suspicion of relapse to intensive investigations to detect early recurrences; unfortunately there are no data to show that early detection of local recurrence by endoscopy or CT improves survival or quality of life because these recurrences are invariably incurable.²⁷
- Isolated liver metastasis identified on CT, however, may be resectable.
- Tumor markers have been used with some success to detect subclinical recurrences and could be used to target more invasive or expensive procedures.^{27,28} The National Academy of Clinical Biochemistry does not recommend the routine use of CEA or carbohydrate antigen 19–9 for postoperative monitoring of patients with gastric cancer.²⁹ **SOR B**

PATIENT EDUCATION

- Surgery with perioperative chemotherapy is potentially curative; operative mortality is approximately 3%.²¹
- Early postoperative complications include anastomotic failure, bleeding, ileus, cholecystitis, pancreatitis, pulmonary infections, and thromboembolism. Further surgery may be required for anastomotic leaks.¹¹
- Late mechanical and physiologic complications include dumping syndrome, vitamin B₁₂ deficiency, reflux esophagitis, and bone disorders, especially osteoporosis.
- Postgastrectomy patients often are immunologically deficient.

61 LIVER DISEASE

Mindy A. Smith, MD, MS
Angie Mathai, MD

PATIENT STORY

A 64-year-old woman presents with complaints of itchy skin and fatigue. She is noted on physical examination to have scleral icterus and jaundice (**Figure 61-1**). Laboratory testing revealed elevated liver enzymes, particularly the serum alkaline phosphatase and γ -glutamyltranspeptidase, and positive antinuclear and antimitochondrial antibodies. A liver biopsy confirmed primary biliary cirrhosis. Two months later, she vomited up some blood and on endoscopy was found to have esophageal varices from her portal hypertension (**Figure 61-2**).

INTRODUCTION

Liver disease can be caused by any number of metabolic, toxic, microbial, circulatory, or neoplastic insults resulting in direct liver injury or from obstruction of bile flow or both. Liver injury falls anywhere on the spectrum from transient abnormalities in biomarkers to life-threatening multiorgan failure.

SYNONYMS

The following terms refer to various types of liver diseases: hepatic failure, hepatic dysfunction, alcoholic hepatitis, viral hepatitis, cirrhosis, hepatocellular disease, cholestatic disease, liver fibrosis.

EPIDEMIOLOGY

Common causes of liver disease include:

- Nonalcoholic fatty liver disease (NAFLD)—Present in 10% to 30% of adults in the general population; now the most common cause of chronic liver disease in Western countries.¹ NAFLD is believed responsible for 90% of cases of elevated liver enzymes without an identifiable cause (e.g., viral hepatitis, alcohol, genetic, medications).²
- Alcohol, excessive use—Approximately 5% of the population are at risk; this includes women who drink more than two drinks per day and men who drink more than three drinks per day.³
- Drug-induced liver disease:⁴
 - Drugs causing hepatitis include phenytoin, captopril, enalapril, isoniazid, amitriptyline, and ibuprofen.
 - Drugs causing cholestasis include oral contraceptives, erythromycin, and nitrofurantoin.
 - Drugs causing both of the above include azathioprine, carbamazepine, statins, nifedipine, verapamil, amoxicillin/clavulanic acid, and trimethoprim-sulfamethoxazole.

FIGURE 61-1 Scleral icterus in a 64-year-old Hispanic woman with primary biliary cirrhosis. (Courtesy of Javid Ghandehari, MD.)

FIGURE 61-2 Esophageal varices in the patient in **Figure 61-1** secondary to her cirrhosis and portal hypertension. (Courtesy of Javid Ghandehari, MD.)

- Infectious disease—Viral hepatitis, infectious mononucleosis, *Cytomegalovirus*, and coxsackievirus are most common. Viral hepatitis infections include:
 - Hepatitis A—Twenty-nine percent to 33% of patients have ever been infected with hepatitis A; there are no chronic infections.⁵ Incidence rates in recent years have declined with approximately 1987 cases reported and 9000 estimated in 2009.⁶
 - Hepatitis B—Five percent to 10% of volunteer blood donors in the United States have evidence of prior infection, with 1% to 10% of those infected progressing to chronic hepatitis B virus (HBV) infection.⁵ Up to 1.4 million people have chronic hepatitis B.⁶
 - Hepatitis C—In the United States, 1.8% of the general population have had hepatitis C, with 50% to 70% developing chronic hepatitis and 80% to 90% chronic infection.⁵ Nearly 3.9 million have chronic hepatitis C.⁶
 - Hepatitis D—Transmitted through contact with infectious blood and can occur as a coinfection or as a superinfection in persons with HBV infection.⁶
 - Hepatitis E— Outbreaks are usually associated with contaminated water supply in countries with poor sanitation.⁶

Less common disorders include:

- Genetic inheritance—Wilson disease (defective copper transport with copper toxicity; autosomal recessive with 1 per 40,000 affected), hemochromatosis (disorder of iron storage; autosomal recessive—among individuals of northern European heritage, 1 in 10 individuals is a heterozygous carrier and 0.3% to 0.5% have the disease), α_1 -antitrypsin deficiency (autosomal recessive with 1% to 2% of patients with chronic obstructive pulmonary disease affected).
- Autoimmune liver disease—Eleven percent to 23% of patients with chronic liver disease and accounts for approximately 6% of liver transplantations in the United States.⁷
- Primary biliary cirrhosis (approximately 5 per 100,000 persons worldwide)—A disease of unknown etiology characterized by inflammatory destruction of the small bile ducts and gradual liver cirrhosis (**Figures 61-1** and **61-2**).

ETIOLOGY AND PATHOPHYSIOLOGY

To understand liver disease, the anatomy and key functions are briefly described here.

- The hepatic artery (20%) and the portal vein (80%) provide the vascular supply of the liver.³ The liver is organized functionally into acini, which are divided into three zones³:
 - Zone 1—The portal areas where blood enters from both sources.
 - Zone 2—The hepatocytes and sinusoids where blood flows.
 - Zone 3—The terminal hepatic veins.
- Hepatocytes, the predominant cells in the liver, perform several vital functions, including the synthesis of essential serum proteins (e.g., albumin, coagulation factors); production of bile and its carriers (e.g., bile acids, cholesterol); regulation of nutrients (e.g., glucose, lipids, amino acids); and metabolism and conjugation of

lipophilic compounds (e.g., bilirubin, various drugs) for excretion into the bile or urine.³

- There are two basic patterns of liver disease and one mixed pattern:³
 - Hepatocellular—Features of this type are direct liver injury, inflammation, and necrosis. Examples are alcoholic and viral hepatitis.
 - Cholestatic (obstructive)—Involves inhibition of bile flow. Examples are gallstone disease, malignancy, primary biliary cirrhosis, and some drug-induced disease.
 - Both patterns—Evidence of direct damage and obstruction. Examples are cholestatic form of viral hepatitis and some drug-induced diseases.
- Cirrhosis occurs following irreversible hepatic injury with hepatocyte necrosis resulting in fibrosis and distortion of the vascular bed. This, in turn, can cause portal hypertension.
- The spectrum of NAFLD ranges from hepatic steatosis (fat deposition in liver cells) to nonalcoholic steatohepatitis (NASH) and cirrhosis.² In NAFLD, steatosis occurs when free fatty acids, released in the setting of insulin resistance, are taken up by the liver; the same process can occur in alcoholism. The presence of these fatty acids leads to inflammation from other insults to the liver including oxidative stress, upregulation of inflammatory mediators, and dysregulated apoptosis, producing NASH, fibrosis, and sometimes cirrhosis (occurs in approximately 20% of patients with NASH).²

RISK FACTORS

- Risk factors for liver disease include:³
 - Alcohol and intravenous drug use.
 - Drugs (e.g., oral contraceptives).
 - Personal and sexual habits.
 - Travel to underdeveloped countries.
 - Exposure to contaminant in food (e.g., shellfish) or individuals with liver disease (includes needle stick injuries).
 - Family history.
 - Blood transfusion prior to 1992.
- Obesity and the metabolic syndrome are risk factors for NAFLD and the more advanced form NASH.

DIAGNOSIS

The goals of diagnosis are to determine the etiology and severity of the liver disease, and, where appropriate, the stage of the disease, including whether it is acute or chronic, early or late in the course of the disease, and whether there is cirrhosis present and to what degree.

CLINICAL FEATURES

- Patients with NAFLD are usually asymptomatic.
- Constitutional symptoms in patients with liver disease include fatigue (most common; especially following activity), weakness, anorexia, and nausea.
- Skin alterations:³
 - Jaundice (hallmark of obstructive pattern)—Best seen in the sclera or below the tongue; the latter is particularly useful in

dark-skinned individuals. Not detected until serum bilirubin levels reach 2.5 mg/dL (43 μ mol/L). Early, jaundice may manifest as dark (tea colored) urine and later with light-colored stools. Jaundice without dark urine is usually from indirect hyperbilirubinemia, as seen in patients with hemolytic anemia or Gilbert syndrome.

- Palmar erythema—Can be seen in both acute and chronic disease but also seen in normal individuals and during pregnancy (**Figure 61-3**).
- Spider angiomas (superficial, tortuous arterioles that flow outward from the center)—Also seen in both acute and chronic disease, in normal individuals, and during pregnancy (**Figure 61-4**).
- Excoriations—Pruritus is prominent in acute obstructive disease and in chronic cholestatic diseases such as primary biliary cirrhosis.
- Palpable purpura—Seen with hepatitis C and chronic HBV.
- Abdominal distention/bloating—Secondary to ascites (accumulation of excess fluid within the peritoneal cavity) (**Figure 61-5**).
 - Ascites may be detected on examination by shifting dullness on percussion (ascitic fluid will flow to the most dependent portions of the abdomen and the air-filled intestines will float on top of this fluid. The fluid–air interface is detected with the patient supine and then turned onto the side where the “line” shifts upward) (**Figures 61-6 and 61-7**).
- Pain in the right upper quadrant (caused by stretching or irritation of the Glisson capsule surrounding the liver) with tenderness on examination in the liver area. Pain and fever in a patient with ascites should suggest the diagnosis of spontaneous bacterial peritonitis (SBP).
- Hepatomegaly and splenomegaly (congestive splenomegaly from portal hypertension)—Seen in patients with cirrhosis, venoocclusive disease, malignancy, and alcoholic hepatitis.³
- Features of hyperestrogenemia in men including gynecomastia (**Figure 61-8**) and testicular atrophy.
- Physical signs of specific liver disease include:
 - Kayser-Fleischer rings—Brown copper pigment deposits around the periphery of the cornea seen in Wilson disease (**Figure 61-9**).
 - Excessive skin pigmentation (slate gray hue/bronzing), diabetes mellitus, polyarticular arthropathy, congestive heart failure, and hypogonadism (hemochromatosis).
 - Cachexia, wasting, and firm hepatomegaly (primary hepatocellular carcinoma or metastatic liver disease).
- Features of patients with advanced disease include muscle wasting, ascites, edema, dilated abdominal veins (e.g., caput medusae—collateral veins seen radiating from the umbilicus), bruising, hepatic fetor (i.e., sweet, ammonia odor), asterixis (i.e., flapping of the hands when extended), and mental confusion, stupor, or coma.³
- Hepatic failure, defined as the occurrence of signs and symptoms of hepatic encephalopathy, may begin with sleep disturbance, personality changes, irritability, and mental slowness.³ Mental confusion, disorientation, or coma may occur later along with physical signs as above.

LABORATORY TESTING

- Initial evaluation with bilirubin, albumin, alanine aminotransferase (ALT), aspartate aminotransferase (AST), γ -glutamyl transpeptidase

FIGURE 61-3 Palmar erythema in a man with cirrhosis secondary to alcoholism. (Courtesy of Richard P. Usatine, MD.)

FIGURE 61-4 Spider angioma on the face of a woman with cirrhosis secondary to chronic hepatitis C. (Courtesy of Richard P. Usatine, MD.)

FIGURE 61-5 Tense ascites in a woman with cirrhosis from her alcoholism. An umbilical hernia is also seen from the increased intraabdominal pressure. (Courtesy of Richard P. Usatine, MD.)

(GGT), and alkaline phosphatase (AlkP).³ **Table 61-1** provides the diagnostic interpretation of the patterns of liver biochemical markers.

- In acute disease (duration <6 months) with a hepatocellular pattern (see **Table 61-1**) consider infections, ingestions, or Wilson disease.
- In acute disease with a cholestatic pattern (see **Table 61-1**) consider obstructing gallstones or masses, primary biliary cirrhosis and cholangitis
- In chronic disease (duration >6 months) with hepatocellular pattern (see **Table 61-1**) or mixed pattern (\uparrow ALT, \uparrow AlkP), consider hemochromatosis, Wilson disease, and α_1 -antitrypsin deficiency. Because many of the acute processes can also cause a chronic picture, consider workup for hepatitis B or C, autoimmune hepatitis, alcoholic disease, chronic drug ingestion, or structural abnormalities.
- In chronic disease with cholestatic pattern, consider primary sclerosing cholangitis (see **Table 61-1**).
- In patients with NAFLD, elevations in ALT and AST are usually no more than 4 times the upper limit of normal; ALT usually predominates.²
- Bilirubin, albumin, and prothrombin time along with the presence or absence of ascites and hepatic encephalopathy are part of the Child-Pugh classification of cirrhosis that has been used to estimate the likelihood of survival and complications of cirrhosis; it is also used to determine candidacy for liver transplantation.⁸ Another scoring system, the model for end-stage liver disease (MELD), which uses the international normalized ratio, serum bilirubin, and serum creatinine, is a reliable measure of mortality risk in patients with end-stage liver disease and used to prioritize liver transplantations.⁹ In 2011, the MeSO index was published; it adjusts the MELD score by including serum sodium and may be more useful in determining prognosis in patients with decompensated cirrhosis than the MELD alone.¹⁰
- Suspected SBP can be confirmed following paracentesis of the ascitic fluid showing a polymorphonuclear leukocyte count greater than or equal to 250 cells/mm.⁵
- It may be possible to predict significant fibrosis and inflammation among patients with chronic hepatitis B using noninvasive markers, thereby limiting the number of biopsies needed. Serum microRNA profiles may serve as noninvasive biomarkers for HBV infection.¹¹ The aspartate aminotransferase-to-platelet ratio index (APRI) is a new marker that can identify hepatitis C-related fibrosis with a moderate degree of accuracy. This information may limit biopsies in patients with chronic hepatitis C.¹²
- In one study, significant liver fibrosis was predicted in patients who were hepatitis B e antigen (HBeAg)-negative using the HBV DNA levels, AlkP, albumin, and platelet counts with an area under Receiver Operating Characteristic curve of 0.91 for the training group and 0.85 for the validation group.¹³
- The best model for predicting significant inflammation included the variables age, HBV DNA levels, AST, and albumin with an area under the curve of 0.93 in the training and 0.82 in the validation group. In HBeAg-positive patients, no factor could accurately predict stages of liver fibrosis, but the best factor for predicting significant inflammation was AST with an area under the curve of 0.87.

IMAGING

Ultrasound is best for detection of NAFLD. It is most accurate when there is greater than 30% steatosis; use of liver elasticity can help distinguish severe from mild fibrosis.² MRI reliably detects lesser degrees of steatosis (down to 3%). NAFLD can usually be diagnosed by history, serologies, and abdominal imaging, although biopsy may be needed to judge severity.

BIOPSY

Liver biopsy is the gold standard for diagnosing those with acute disease where the etiology is unclear or for those with chronic disease (e.g., chronic hepatitis B, hepatitis C) to assist in staging the disease and for prognosis.

MANAGEMENT

Management decisions are based on the etiology, acuity, and severity of the disease.

- NAFLD/NASH—Diet and exercise have been shown to decrease liver enzymes, although it is not known if there is histologic improvement as well.² Other treatments for obesity, such as medication or bariatric surgery, may also be useful. Because NAFLD increases risk of cardiovascular disease,¹ treatment of other risk factors, such as hypertension and hyperlipidemia, should be undertaken. It is not known whether use of insulin sensitizers, such as metformin, and thiazolidinediones or statins specifically for NAFLD are beneficial.
- Alcoholic cirrhosis—Discontinue alcohol and provide supportive therapy. Alcoholic hepatitis is treated with either glucocorticoids or pentoxifylline based on Maddrey Discriminant Function (MDF).¹⁴
- Drug-induced disease—Withdrawal of agent. Routine screening of asymptomatic patients on statins is no longer recommended. Withdrawal of statins usually results in resolution of elevated transaminases within 2 months. The same statin could be continued at a lower dose or another statin could be started.¹⁵
- Viral hepatitis—Hepatitis A and acute hepatitis B are treated supportively; virtually all patients recover without specific treatment. Chronic hepatitis B may be treated with antiviral therapy (interferon) and the nucleoside analog lamivudine or the acyclic nucleotide analog adefovir.^{5,16} Hepatitis C is currently treated with pegylated interferon and ribavirin.⁵ All persons with chronic hepatitis B who are not immune to hepatitis A should receive 2 doses of hepatitis A vaccine 6 to 18 months apart.¹⁵ Patients with hepatitis C should be vaccinated against hepatitis A and hepatitis B if they are seronegative for these other forms of hepatitis. **SOR B** Newborns of HBV-infected mothers should receive hepatitis B immunoglobulin and hepatitis B vaccine at delivery and complete the recommended vaccination series.¹⁵ **SOR A**
- Wilson disease is treated with zinc acetate (50 mg 3 times daily) with or without trientine, a chelating agent (500 mg twice daily).¹⁷
- Hemochromatosis is treated with weekly or twice weekly phlebotomy.
- Primary biliary cirrhosis is managed with ursodiol (13 to 15 mg/kg per day) single dose in the presence of abnormal liver function tests

regardless of histologic stage and eventual liver transplantation.^{18,19}
SOR A In a metaanalysis of 7 trials, ursodeoxycholic acid treatment resulted in a significant reduction of the incidence of liver transplantation (odds ratio [OR] 0.65, $p = 0.01$) and a marginally significant reduction of the rate of death or liver transplantation.²⁰ Bile acid sequestrants can be used for pruritis.²⁰

- Autoimmune hepatitis is treated with glucocorticoid therapy with or without azathioprine. Oral budesonide, in combination with azathioprine, induces and maintains remission in patients with non-cirrhotic autoimmune hepatitis, with a low rate of steroid-specific side effects.²¹

Management of the complications of cirrhosis include:

- Control ascites with salt restriction (2g per day of NaCl), fluid restriction if hyponatremic (1000 mL per day), gentle diuresis to avoid electrolyte disturbance (spironolactone 100 to 400 mg per day) with or without furosemide (40 to 160 mg per day).¹⁸ **SOR A**
- SBP is treated with empiric antibiotic therapy (e.g., intravenous cefotaxime 2 g every 8 hours).²² **SOR A**
- Portal hypertension may be managed with shunting.

PREVENTION AND SCREENING

- Maintaining normal weight and treating obstructive sleep apnea and diabetes may help prevent NAFLD.
- Screen for alcohol abuse using structured questionnaires (e.g., CAGE [cutting, annoyance, guilt, eye-opener], Alcohol Use Disorders Identification Test [AUDIT]). Encourage abstinence and consider naltrexone or acamprosate in combination with counseling.²³
- Risk for hepatitis A can be minimized by avoidance of susceptible foods in high-risk countries.
- For hepatitis B, recommendations include avoidance of high-risk behavior and blood contact, vaccination of risk groups, postexposure prophylaxis with anti-hepatitis B immunoglobulin, and cleaning of wound after exposure to infectious blood.²⁴
- Screen for HBV infection in pregnant women at their first prenatal visit.²⁵ Patients with chronic liver disease should be vaccinated with hepatitis A and hepatitis B vaccines.²⁶
- Hepatitis C risk can be decreased by avoidance of intravenous drug use, tattooing, and unprotected sexual intercourse.
- Screen patients with mild elevations of liver enzymes (above normal but less than 5 times the upper limit of normal) for hepatitis B and hepatitis C.²⁷

PROGNOSIS

- Thirty percent of patients with NAFLD show histologic progression of fibrosis over 5 years and approximately 3% eventually develop cirrhosis.² Of those with NASH, 15% to 20% may develop cirrhosis. Leading causes of death appear to be cardiovascular disease, cancer (including hepatocellular carcinoma), and liver-related disease. Recurrence of hepatocellular carcinoma is higher in patients with NASH.²
- Patients presenting with a high clinical suspicion of alcoholic hepatitis should have their risk for poor outcome stratified using

the MDF. Continued alcohol use is associated with disease progression.²³

- Most cases of hepatitis B are self limiting. If the hepatitis B surface antigen (HBsAg) test remains positive 6 months after the disease onset, the patient is likely to have become a hepatitis B carrier. The carrier status is confirmed by a positive HBsAg test at 12 months.²⁴
- Hepatitis C becomes chronic more often than hepatitis B; this occurs in approximately 50% to 80% of patients. The average time from primary infection to liver disease to cirrhosis is 21 years. Twenty percent to 30% develop cirrhosis as early as 5 to 7.5 years after contracting the disease. Treatment is more effective for genotypes 2 and 3 than for genotypes 1 and 4.²⁴
- Approximately 50% of patients with autoimmune hepatitis will die within 5 years without treatment. Steroids can induce remission with survival rates similar to the general population.⁷ The majority of patients with autoimmune hepatitis achieves complete remission within 3 months but requires long-term or permanent immunosuppressive therapy; such therapy is usually well tolerated. Long-term survival in well-managed patients is excellent.²⁸
- In the absence of cirrhosis and diabetes, phlebotomy prevents further tissue damage and guarantees a normal life expectancy in patients with hemochromatosis.²⁹
- Primary sclerosing cholangitis is a progressive process with a probability of transplant-free survival of 18 years in asymptomatic patients and of 8.5 years in symptomatic patients.³⁰

FOLLOW-UP

- Hepatitis B virus carriers with high risk for hepatocellular carcinoma (HCC) (e.g., men older than 45 years of age, those with cirrhosis, and individuals with a family history of HCC), should be screened periodically with both α -fetoprotein and ultrasonography.¹⁶ **SOR C**
- Patients who have survived an episode of SBP should receive long-term prophylaxis with daily norfloxacin or trimethoprim-sulfamethoxazole.²² **SOR A**

PATIENT EDUCATION

- Patients with liver disease should be counseled about avoidance of alcohol and medications that may cause liver injury. They should avoid aspirin use (coagulation impaired) and use acetaminophen at lower doses (2 g per day).
- For those with infectious causes of liver disease, prevention of the spread of disease should be emphasized including limiting alcohol, safe-sex practices, and avoiding needle sharing. Screening for sexual contacts and household members should be offered along with vaccination for hepatitis B, if nonimmune and noninfected.¹⁶ **SOR A**

62 GALLSTONES

Mindy A. Smith, MD, MS

PATIENT STORY

A 44-year-old woman reports frequent episodes of severe pain in the mid and upper right-side of her abdomen that usually occurs shortly after her evening meal and sometimes at night. She is obese, but otherwise healthy. The pain lasts for several hours and is steady and often causes vomiting. On physical examination she complains of slight tenderness in the right upper quadrant (RUQ). An ultrasound confirms the presence of gallstones (**Figure 62-1**).

INTRODUCTION

Gallstones are concretions (inorganic masses), usually composed of cholesterol, that form in the gallbladder or bile duct. They are formed by concretion (joining together of adjacent parts and hardening) or accretion (growth by addition or adherence of parts normally separated) of normal and/or abnormal bile constituents.

EPIDEMIOLOGY

- Based on autopsy data, 20% of women and 8% of men have gallstones.¹
- Approximately 20 million people in the United States are affected, with 1 million new cases each year.¹
- In a Swedish incidence study of 621 randomly selected individuals ages 35 to 85 years, 42 (8.3%) of the 503 subjects available at 5 years developed gallstones; this yielded an incidence for newly developed gallstones of 1.39 per 100 person-years.²
- Among pregnant women, 5% to 12% have gallstones and 20% to 30% have gallbladder sludge (thick mucous material containing cholesterol crystals and mucin thread or mucous gels). Gallbladder sludge is a possible precursor form of gallstone disease.¹
- Patients with asymptomatic gallstones have a 1% to 2% risk per year of developing symptoms or complications of gallstones. Based on data primarily for men, this will occur in 10% by 5 years, 15% by 10 years, and 18% by 15 years following diagnosis.¹
- Gallstone disease is responsible for approximately 10,000 deaths per year in the United States. Most (7000) of these deaths are attributable to acute gallstone complications (e.g., cholecystitis, pancreatitis, cholangitis).³
- Although gallbladder cancers most often occur in the setting of stones (91% of 34 patients with gallbladder cancer in one study),⁴ gallbladder cancer is rare. An incidence rate of 0.28% for incidental gallbladder carcinoma was reported in a Swiss database study of a population of more than 30,000 patients undergoing laparoscopic cholecystectomy.⁵

FIGURE 62-1 Ultrasound showing two echogenic gallstones in the gallbladder. Note the absence of echoes posterior to the gallstone called “shadowing” (arrowheads). (From Schwartz’s *Principles of Surgery, Ninth Edition*, New York, NY: McGraw-Hill; 2010:1141, Fig. 32-6. Copyright 2010, McGraw-Hill.)

ETIOLOGY AND PATHOPHYSIOLOGY

- There are two types of gallstones: cholesterol stones (80%) and pigmented stones (primarily calcium bilirubinate, 20%).
- The solute components of bile include bile acids (80%), lecithin and other phospholipids (16%), and unesterified cholesterol (4%).¹ Cholesterol gallstones form when there is excess cholesterol or an abnormal ratio of cholesterol, bile acids, and lecithin.
- Excess biliary cholesterol can occur from a secondary increase in secretion of cholesterol caused by obesity, high cholesterol diet, clofibrate therapy, or a genetic predisposition to increased hydroxymethylglutaryl-coenzyme A reductase.
- The excess cholesterol becomes supersaturated and can precipitate out of solution in a process called *nucleation*, forming solid cholesterol monohydrate crystals that can become trapped in gallbladder mucus, producing sludge, and/or grow and aggregate to form cholesterol gallstones.
- Gallbladder hypomotility is a predisposing and possibly necessary factor in stone formation because of the failure to completely empty supersaturated or crystal-containing bile.¹ Situations associated with hypomotility include pregnancy, prolonged parenteral nutrition, surgery, burns, and use of oral contraceptives or estrogen therapy.
- Pigmented stones occur when increasing amounts of unconjugated bilirubin in bile precipitate to form stones. Bilirubin, a yellow pigment derived from the breakdown of heme, is actively secreted into bile by liver cells. In situations of high heme turnover, such as chronic hemolytic states (e.g., sickle cell anemia), calcium bilirubinate can crystallize from solution and form stones.
- Chronic gallstones may cause progressive fibrosis of the gallbladder wall and loss of function.

RISK FACTORS

- Genetic mutations can result in reduction of bile acids and lecithin that predispose some patients to stone formation. A high prevalence of gallstones is found in first-degree relatives of patients with gallstones and among Native Americans, Chilean Indians, and Chilean Hispanics.¹
- In a case-control study, the prevalence of gallstones was 28.6% in first-degree relatives of subjects with gallstones versus 12.4% in first-degree relatives of subjects without gallstones (relative risk [RR] 1.80, 95% confidence interval [CI] 1.29 to 2.63).³
- Other risk factors for gallstones include rapid weight loss (10% to 20% of these patients form stones),¹ increasing age, liver or ileal disease, and cystic fibrosis.

DIAGNOSIS

CLINICAL FEATURES

- Symptoms of gallstones are caused from inflammation or obstruction as stones migrate into the cystic or common bile duct (CBD).

- Biliary colic is a steady, severe pain or ache, usually of sudden onset, located in the epigastrium or RUQ. Pain episodes last between 30 minutes and 5 hours and may radiate to the interscapular area, right scapula, or right shoulder.
- Gallstone-related pain may be precipitated by a fatty meal, a regular meal or a large meal followed by a prolonged fast.
- Pain is recurrent and often nocturnal.
- RUQ tenderness may be elicited on physical examination.
- Nausea and vomiting are common.
- Accompanying fever and chills suggests a complication of gallstones. Complications are more common in patients with a calcified gallbladder or in those who have had a previous episode of acute cholecystitis.¹

LABORATORY STUDIES

- No laboratory testing is usually indicated as the results are usually normal. However, an elevated γ -glutamyl transpeptidase suggests a CBD stone. In a study of patients with acute calculous gallbladder disease, investigators found a 1-in-3 chance of CBD stones when the γ -glutamyl transpeptidase level was above 90 U/L and a 1-in-30 chance when the level was less than 90 U/L.⁶

IMAGING

- Ultrasound is the diagnostic test of choice and is 95% accurate for stones as small as 2 mm in diameter (**Figure 62-1**).¹ Shadowing, a discrete acoustic shadow caused by the absorption and reflection of sound by the stone that changes with patient positioning, is an important diagnostic feature that is shown in **Figures 62-1** and **62-2**.
- In one study, high-resolution ultrasound was more accurate than endoscopic ultrasonography or CT in differentiating benign disease from malignancy in cases with gallbladder polypoid lesions.⁷
- Gallstones may be seen on plain film, but only calcified stones are seen (**Figures 62-3** and **62-4**). This includes only 10% to 15% of cholesterol stones and 50% of pigmented stones.¹ Stones may be single or multiple and the gallbladder wall may be calcified (referred to as a *Porcelain gallbladder*), indicating severe chronic cholecystitis or adenocarcinoma.
- CT is less sensitive and more expensive than ultrasound for the detection of gallstones (**Figures 62-5** and **62-6**). However, CT can detect both radiopaque stones and radiolucent stones.
- An oral cholecystogram can be used to assess cystic duct patency and emptying function. This test has largely been replaced by gallbladder ultrasound.
- Radioisotope scans (e.g., technetium [Tc]-99m hepatiminodiacetic acid [HIDA]) can be used to confirm acute cholecystitis (nonvisualizing gallbladder) and can be useful in evaluating functional abnormalities.
- Endoscopic retrograde cholangiopancreatography is used for imaging bile ducts. Stones in bile appear as filling defects in the opacified ducts. Endoscopic retrograde cholangiopancreatography is usually performed in conjunction with endoscopic retrograde sphincterotomy and gallstone extraction.

FIGURE 62-2 Gallstones visible in the gallbladder of a 43-year-old woman with right upper quadrant pain and a positive Murphy sign. (Courtesy of Jeff Russell, MD.)

FIGURE 62-3 Plain film showing multiple gallstones (white arrow). (From Schwartz DT, Reisdorff EJ. *Emergency Radiology*. New York: McGraw-Hill; 2000:536, Fig. 19-37. Copyright 2000, McGraw-Hill.)

DIFFERENTIAL DIAGNOSIS

Severe epigastric and RUQ pain can be seen in the following conditions:

- Acute cholecystitis—Pain may radiate to the back, and fever is usually present. Physical examination can reveal RUQ rigidity and guarding with a positive Murphy sign (RUQ pain worsening with deep inspiration while the examiner maintains steady pressure below the right costal margin). White blood count, serum amylase, aspartate transaminase, and alanine transaminase may all be elevated.
- Pancreatitis—Pain is located in the midepigastrium and left upper quadrant, but may radiate to the RUQ. Abdominal distention and diminished bowel sounds may be present. Elevations in lipase and amylase are found and pancreatic pseudocysts or abscess may be present on ultrasound.
- Peptic ulcer disease—Pain may be described as burning and is usually epigastric and often relieved by antacids. Onset is 1 to 3 hours after meals or following nonsteroidal antiinflammatory drug usage. Stool hemoccult testing may be positive. An ulcer may be visualized on upper GI barium swallow or endoscopy (Chapter 59, Peptic Ulcer Disease).
- Hepatitis—Other symptoms and signs include malaise, anorexia, pruritus, tender liver, and low-grade fever. Jaundice may be present and urine may be dark (i.e., bilirubinuria). Aspartate transaminase and alanine transaminase are elevated (Chapter 61, Liver Disease).

MANAGEMENT

- Silent gallstones may be managed expectantly; prophylactic cholecystectomy is unwarranted based on the few who develop symptoms over time and the very low rate of complications (3% to 4%).⁸ There are no randomized controlled trials comparing cholecystectomy to watchful waiting for silent gallstones.⁹ **SOR C**
- Cholecystectomy should be considered for patients with:¹
 - Frequent symptoms that interfere with daily life.
 - A prior complication of gallstone disease.
 - The presence of an underlying condition (e.g., calcified gallbladder) that predisposes the patient to increased risk of complications.
- Laparoscopic cholecystectomy is the surgical treatment of choice because of the low rate of complications (4%) and mortality (<0.1%), shortened hospital stay, and reduced cost.¹ Conversion to an open laparotomy is infrequent (5%).¹ A Cochrane review found no differences in mortality or complications among open, small-incision, and laparoscopic cholecystectomy, but quicker recovery favors minimally invasive procedures; small-incision cholecystectomies appear to have shorter operative time and lower cost.¹⁰
- Early laparoscopic cholecystectomy (<7 days from symptom onset) during acute cholecystitis has comparable outcomes to delayed cholecystectomy and shortens hospital stay.¹¹
- Single versus four-port laparoscopic cholecystectomy may reduce postoperative pain.¹²
- For patients with gallbladder and CBD stones, intraoperative endoscopic sphincterotomy during laparoscopic cholecystectomy appears as safe and effective as preoperative endoscopic

FIGURE 62-4 Gallstone ileus in an elderly patient with diabetes; note dilated loops of small bowel and an ectopic gallstone (arrow). (From Schwartz DT, Reisdorff EJ. *Emergency Radiology*. New York: McGraw-Hill; 2000:527, Fig. 19-21. Copyright 2000, McGraw-Hill.)

FIGURE 62-5 CT scan showing two large gallstones that have a rim of calcification (large arrows). (From Schwartz DT, Reisdorff EJ. *Emergency Radiology*. New York: McGraw-Hill; 2000:538, Fig. 19-41A. Copyright 2000, McGraw-Hill.)

sphincterotomy followed by laparoscopic cholecystectomy and is associated with significantly shorter hospital stay.¹³

- Medical therapy with ursodeoxycholic acid may be considered for patients with functioning gallbladders and small stones (<10 mm).¹ Approximately 50% of these patients will have complete dissolution of stones in 6 to 24 months, but recurrences are common (see “Prognosis” below).¹
- Medical therapy can also be used to prevent gallstone formation in patients with expected rapid weight loss caused by very-low-calorie diets or bariatric surgery. In one study, ursodeoxycholic acid at a dose of 500 mg daily for 6 months reduced the incidence of gallstones over placebo (3% vs. 22%, respectively, at 12 months) and cholecystectomy (4.7% vs. 12%, respectively).¹⁴
- Extracorporeal shock wave lithotripsy combined with medical therapy may be considered for patients with radiolucent, solitary stones less than 2 cm, and a functional gallbladder.¹

PROGNOSIS

- Abdominal pain resembling biliary colic may persist in up to 30% of patients despite cholecystectomy (called postcholecystectomy syndrome).¹⁵ In one follow-up survey of 1300 patients following cholecystectomy (44% response rate), preoperative pain resolved in 90% but postoperative pain was reported in 25%; in 10% of these patients the post-operative pain was the same quality and location as the preoperative pain, and in 17% a new abdominal pain developed, most often in the periumbilical area.¹⁶ In a study of 100 consecutive patients, 13% had persistent pain following laparoscopic cholecystectomy.¹⁷
- In the follow-up survey noted above (N = 573), nonpain symptoms all decreased in prevalence following cholecystectomy, including indigestion (14%), fatty food intolerance (19%), and heartburn (13%). Diarrhea, however, was present in similar percentages pre- and postoperatively (19% and 21%, respectively).¹⁶
- Following medical therapy, recurrences are common (30% to 50% at 3- to 5-year follow-up).¹

FOLLOW-UP

- Approximately 5% to 10% of patients develop chronic diarrhea, attributed to increased bile salts reaching the colon, following cholecystectomy. Diarrhea is usually mild and can be managed with over-the-counter antidiarrheal agents (e.g., loperamide).
- Postcholecystectomy pain may be related to recurrent stones, choledocholithiasis, biliary dyskinesia, inflammatory scarring or strictures involving the sphincter of Oddi or the CBD, and dilation of cystic duct remnants; ultrasound, CT, cholangiography, or magnetic resonance cholangiopancreatography may be useful in identification of the cause and some may be amenable to surgical management.^{18,19}

PATIENT EDUCATION

- Patients with asymptomatic gallstones may be managed expectantly—The rates of developing symptoms and complications should be

FIGURE 62-6 Radiographic Mercedes-Benz sign seen on a CT cut through the gallbladder (the gallstones produce a black pattern that resembles a Mercedes-Benz logo in the center). (Courtesy of Mike Freckleton, MD.)

reviewed. They should be encouraged to report symptoms of biliary colic and acute cholecystitis or pancreatitis (described above).

- Laparoscopic cholecystectomy appears to be very successful for symptom resolution, although chronic diarrhea may occur and abdominal pain may persist or new pain develop in approximately one-quarter of patients.¹⁵

63 COLON POLYPS

Cathy Abbott, MD
Mindy A. Smith, MD, MS

PATIENT STORY

A 62-year-old woman presents to her physician for routine annual examination. She has no known family history of colon disease and is asymptomatic. Stool cards and flexible sigmoidoscopy were recommended and on flexible sigmoidoscopy a 2.4-cm polyp was noted at 35 cm. A colonoscopy was performed and additional polyps were identified in the descending colon and cecum (**Figure 63-1**).

INTRODUCTION

Colon polyps are growths that arise from the epithelial cells lining the colon.

EPIDEMIOLOGY

- More than 30% of middle-aged and elderly patients are found to have adenomatous polyps on screening and based on autopsy surveys; fewer than 1% will become malignant.¹ The lifetime risk of colon cancer is 5.12%.²
- Patients with an adenomatous polyp have a 30% to 50% risk for developing another adenoma and are at higher risk for colon cancer. This risk is greatest in the first 4 years after diagnosis of the first polyp, and greater if a villous adenoma or more than 3 polyps were found.
- Familial adenomatous polyposis of the colon is a rare autosomal dominant disorder. Thousands of adenomatous polyps appear in the large colon, generally by age 25 years, and colorectal cancer develops in almost all of these patients by age 40 years.¹ Other hereditary polyposis syndromes include Gardner syndrome, Turcot syndrome, Peutz-Jeghers syndrome, Cowden disease, familial juvenile polyposis, and hyperplastic polyposis.³

ETIOLOGY AND PATHOPHYSIOLOGY

- There are several types of colon polyps, including:
 - Hyperplastic polyps—These contain increased numbers of glandular cells with decreased cytoplasmic mucus and an absence of nuclear hyperchromatism, stratification, or atypia. Traditionally thought to be benign, recent evidence suggests malignant potential particularly for right-sided polyps, especially proximal hyperplastic serrated polyps¹ and those associated with hyperplastic polyposis syndrome (a familial disorder with multiple [>30] hyperplastic polyps proximal to the sigmoid colon with 2 or more >10 mm).³ The percentage of polyps reported to be in this category ranges from 12% to 90%.^{3,4}

FIGURE 63-1 Colon polyps seen on colonoscopy. (Courtesy of Michael Harper, MD.)

- Adenomatous polyps—These may be tubular, villous (papillary), or tubulovillous. In a case series of 582 patients who had a polyp removed, 81% were adenomatous, including 65.0% that were tubular, 25.8% tubulovillous, 7.2% villous adenomas, and 0.5% mixed adenomatous hyperplastic polyps; 12 (1.4%) were invasive carcinomas.⁴
 - Adenomatous polyps may be pedunculated or sessile; cancers more frequently develop in sessile polyps.¹
- Villous polyps can cause hypersecretory syndromes characterized by hypokalemia and profuse mucous discharge; these more frequently harbor carcinoma in situ or invasive carcinoma than other adenomas.³
- Nonneoplastic hamartoma (juvenile polyp)—These are benign cystic polyps with mucous-filled glands, most commonly found in male children, ages 2 to 5 years, and are often found as singular lesions, but additional polyps are found on panendoscopy in 40% to 50% of children. Juvenile polyps in adolescence may be associated with hereditary syndromes that carry malignant potential.⁵
- A series of genetic/molecular changes have been found that are thought to represent a multistep process from normal colon mucosa to malignant tumor.³ These include:
 - Point mutations in the *K-ras* protooncogene leading to gene activation and deletion of DNA at the site of tumor-suppressor gene.
 - This results in an altered proliferative pattern and polyp formation.
 - Mutational activation of an oncogene, coupled with loss of tumor-suppressor genes, leads to malignant transformation.
 - Serrated polyps, which have in the past been characterized as hyperplastic polyps, are now known to have epigenetic alterations that may develop into colon cancers by another pathway—the CpG-island-methylation-phenotype pathway.⁶
 - Patients with familial polyposis inherit a germline alteration that leads into the above pathway.
- Insulin resistance, with increased concentrations of insulin-like growth factor type I, may also stimulate proliferation of the intestinal mucosa.

RISK FACTORS

- Older age—99% of cases occur in people older than age 40 years and 85% in those older than age 60 years.⁷
- Family history—Present in 10% to 20% of cases.⁷
- Diet appears to be associated with colon polyps and colon cancer. Animal fats may alter anaerobes in the gut microflora, increasing conversion of normal bile acids to carcinogens. Also, increased cholesterol is associated with an enhanced risk of development of adenomas.
- There may be an association between *Helicobacter* exposure and colonic polyps.^{8,9}

DIAGNOSIS

CLINICAL FEATURES

- Usually asymptomatic.
- Patients may experience overt or occult rectal bleeding.

- Change in bowel habits—Diarrhea or constipation can occur, often with decreased stool caliber.
- Secretory villous adenomas can occasionally manifest as a syndrome of severe diarrhea with massive fluid and electrolyte loss.³

TYPICAL DISTRIBUTION

- Cancer distribution is approximately equal between the right and left colon. Juvenile polyps are usually found in the rectosigmoid region.

LABORATORY TESTING

- Occult blood in the stool is found in less than 5% of patients with polyps.¹ Of the 2% to 4% of asymptomatic patients who have heme positive stool on screening, 20% to 30% will have polyps.¹
- For patients with a family history of familial adenomatous polyposis, DNA testing may be performed to detect the adenomatous polyposis coli (*APC*) gene mutation; this can lead to a definitive diagnosis before the development of polyps.¹ **SOR C** A positive test finding only indicates susceptibility, not the actual presence of a polyp.³
- Genetic testing can also be considered for patients with a family history of hereditary nonpolyposis colorectal cancer (HNPCC), which is caused by germline mutation of the DNA mismatch repair genes (*hMLH1*, *hMSH2*, *hPMS1*, *hPMS2*, *hMSH6*).¹⁰ **SOR C**

IMAGING AND ENDOSCOPIC FEATURES

- Polyps may be identified on barium enema (**Figures 63-2** and **63-3**), flexible sigmoidoscopy, or colonoscopy (including virtual computer tomography colonoscopy) (**Figures 63-1** and **63-4**).
- A polyp is defined as grossly visible protrusion from the mucosal surface, although adenomas can also be flat or even depressed.¹¹
- Colonoscopy must be subsequently performed to identify additional lesions and remove all lesions.
- Synchronous lesions occur in one-third of cases (**Figure 63-1**).

BIOPSY

- Polyps upon removal are sent for histology to determine type and whether dysplasia or carcinoma in situ is present (**Figure 63-5**).

DIFFERENTIAL DIAGNOSIS

Other causes of rectal bleeding include:

- Infectious agents—*Salmonella*, *Shigella*, certain *Campylobacter* species, enteroinvasive *Escherichia coli*, *Clostridium difficile*, and *Entamoeba histolytica* can cause bloody, watery diarrhea and are identified by culture. Bacterial toxins may be identified with *C. difficile*. Additional symptoms include fever and abdominal pain, and the disease is often self-limited.
- Hemorrhoids and fissures—Bleeding is usually bright red blood and seen in the toilet or with wiping after bowel movements. Hemorrhoids can sometimes be visible as a protruding mass often associated with pruritus and fissures are identified as a cut or tear

FIGURE 63-2 A 69-year-old female with a family history of colon cancer presented for screening. Her hemocult test was positive. Her double-contrast barium enema (air contrast) demonstrated a large colonic polyp, which was found on surgery to be highly dysplastic. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 63-3 While getting a barium enema for other reasons, this patient was found to have a large colonic polyp. Biopsy of the polyp demonstrated early stage colon cancer, which was treated by surgical resection. (Courtesy of E.J. Mayeaux, Jr., MD.)

occurring in the anus (see Chapter 66, Hemorrhoids). Hemorrhoidal pain is described as a dull ache, but may be severe if thrombosed.

- Diverticula—Bleeding is usually abrupt in onset, painless, and may be massive but often stops spontaneously. These may be seen on endoscopy or on radiographic study.
- Vascular colonic ectasias—Bleeding tends to be chronic, resulting in anemia. Bleeding source may be identified during colonoscopy but a radionuclide scan or angiography may be needed.
- Colon cancer—Other symptoms include abdominal cramping, tenesmus (i.e., urgency with a feeling of incomplete evacuation), narrow caliber stool, occasional obstruction, and, rarely, perforation. Imaging studies often can distinguish and biopsy confirms malignancy (see Chapter 64, Colon Cancer).
- Inflammatory bowel disease—This includes ulcerative colitis and Crohn disease; symptoms include diarrhea, tenesmus, passage of mucus, and cramping abdominal pain (see Chapter 65: Inflammatory Bowel Disease). Extraintestinal manifestations are more common in Crohn disease and include skin involvement (e.g., erythema nodosum), rheumatologic symptoms (e.g., peripheral arthritis, symmetric sacroiliitis), and ocular problems (e.g., uveitis, iritis). Diagnosis may be made on endoscopy.

MANAGEMENT

- Removal of a solitary polyp may be completed during sigmoidoscopy or colonoscopy (**Figure 63-5**).

PREVENTION

- Primary prevention of colon cancer should be encouraged.
 - Dietary alterations may be useful.
 - Decreasing animal fats as diets high in animal fats are thought to be a major risk factor based on epidemiologic studies. However, in the Women's Health Initiative study, a low-fat dietary intervention did not reduce the risk of colorectal cancer in postmenopausal women during 8.1 years of follow-up.¹²
 - Additional dietary fiber has not shown to be helpful in controlled studies.¹³
 - Increasing water consumption to 8 glasses per day may be helpful.
 - Diets high in flavonols (fruits, vegetables, and tea) are associated with decreased risk of colon polyps, possibly by reducing serum interleukin (IL)-6, which is associated with inflammation and carcinogenesis.¹⁴
 - Calcium supplements (1200 mg per day) have been shown to reduce the development of adenomatous polyps.¹⁵ **SOR A**
 - Hormone therapy in women reduces colon cancer incidence.¹⁶ **SOR B**
 - A metaanalysis failed to show that folic acid supplementation reduced the risk of recurrent colon adenomas.¹⁷
 - Low-dose aspirin (81 mg per day) was found to decrease recurrent adenomas, including those containing advanced neoplasms.¹⁸ **SOR B** In patients with familial adenomatous polyposis, once-daily treatment with 25 mg rofecoxib significantly

FIGURE 63-4 Polyp in the cecum seen on colonoscopy. (Courtesy of Marvin Derezin, MD.)

FIGURE 63-5 Polypectomy being performed through the colonoscope. (Courtesy of Marvin Derezin, MD.)

decreased the number and size of rectal polyps in one randomized trial.¹⁹

- Smoking cessation.²⁰
- Increasing physical activity reduces the risk of advanced polyps and neoplasia, possibly by decreasing insulin resistance.²¹

PROGNOSIS

- Patients with a polyp with tubulovillous features or with more than 3 polyps larger than 10 mm are at increased risk for further aggressive lesions on follow-up colonoscopy, and untreated patients with polyps larger than 10 mm are at increased risk for colon cancer both at the site of polyp and at other sites.²²

FOLLOW-UP

- Secondary prevention of colon cancer should be maximized through screening and removal of additional or recurrent polyps or colon cancer in these patients (see Chapter 64, Colon Cancer). Although there is debate regarding the frequency of screening, the American Cancer Society, the U.S. Multi-Society Task Force on Colorectal Cancer, and the American College of Radiology updated guideline recommends repeat colonoscopy at the following intervals:
 - Every 5 to 10 years for those with 1 to 2 small tubular adenomas with low-grade dysplasia after initial polypectomy.
 - Every 3 years for patients with 3 to 10 adenomas or 1 adenoma larger than 1 cm or any adenoma with villous features or high-grade dysplasia.
 - Less than every 3 years for patients with more than 10 adenomas.
 - At 2 to 6 months to verify complete removal in patients with sessile adenomas that are removed piecemeal.²³
- Although screening options that enable detection of both adenomatous polyps and colon cancer include flexible sigmoidoscopy, colonoscopy, double-contrast barium enema, and CT colonography (use of dyes or other visual enhancements during colonoscopy), authors of a Cochrane review found that chromoscopic colonoscopy enhances the detection of polyps in the colon and rectum.²⁴ This form of colonoscopy can be used to identify flat polyps, increasing the sensitivity of colonoscopy, and may allow for detection of high-risk polyps without the need for biopsy.

PATIENT EDUCATION

- Attention to lifestyle factors can contribute to decreasing the risk of colon polyps.
- Patients should be encouraged to undergo screening for colon cancer, including use of high-sensitivity hemoccult cards, flexible sigmoidoscopy, or colonoscopy.²⁵ **SOR A**
- Patients diagnosed with polyps should be encouraged to engage in continued surveillance for polyps and colon cancer. Those at increased risk for a subsequent advanced neoplasia (see above) should have a follow-up colonoscopy at 3 or fewer years.²³ **SOR B** For other patients, follow-up is recommended at 5 to 10 years.¹⁰ **SOR C**

64 COLON CANCER

Mindy A. Smith, MD, MS
Bonnie Wong, MD

PATIENT STORY

A 72-year-old man reports rectal bleeding with bowel movements over the past several months and the stool seems narrower with occasional diarrhea. He has a history of hemorrhoids but at this time is not experiencing rectal irritation or itching, as with previous episodes. His medical history is significant for controlled hypertension and a remote history of smoking. On digital rectal examination, his stool sample tests positive for blood but anoscopy fails to identify the source of bleeding. On colonoscopy, a mass is seen at 30 cm (**Figure 64-1**). A biopsy was obtained and pathology confirmed adenocarcinoma.

INTRODUCTION

Colon cancer is a malignant neoplasm of the colon, most commonly adenocarcinoma. With the establishment of screening programs and treatment improvements, there has been a slow decline in both the incidence and mortality from colon cancer, although it is still a leading cause of cancer death.¹

EPIDEMIOLOGY

- Colon cancer is the third most common cancer in both men and women in the United States, second only to lung cancer as a cause of death.¹
- The incidence and mortality have been slowly but steadily declining in the United States for the past decade.² The American Cancer Society estimated there were 142,570 new cases of colorectal cancer (102,900 colon cancer cases) and 51,370 deaths in 2010.³
- Onset is after age 50 years and peaks at around age 65 years.
- Proximal colon carcinoma rates in blacks are higher than in whites.⁴

ETIOLOGY AND PATHOPHYSIOLOGY

- Colon cancer appears to be a multipathway disease with tumors usually arising from adenomatous polyps or serrated adenomas; mutational events occur within the polyp including activation of oncogenes and loss of tumor-suppressor genes.^{1,5}
- The probability of a polyp undergoing malignant transformation increases for the following cases:¹
 - The polyp is sessile, especially if villous histology or flat.
 - Larger size—Malignant transformation is rare if smaller than 1.5 cm, 2% to 10% if 1.5 to 2.5 cm, and 10% if larger than 2.5 cm.
- Important genes involved in colon carcinogenesis include adenomatous polyposis gene mutations, *KRAS* oncogene, chromosome 18 loss of heterozygosity leading to inactivation of *SMAD4*, and *DCC*

FIGURE 64-1 A sessile colon mass seen at 30 cm. At surgery, this was found to be a Duke stage A adenocarcinoma. (Courtesy of Michael Harper, MD.)

tumor-suppression genes (deleted in colon cancer). Other mutations in genes, such as *MSH2*, *MLH1*, and *PMS2*, result in what is known as high-frequency microsatellite instability (H-MSI), which is found in cases of hereditary nonpolyposis colon cancer and in approximately 20% of sporadic colon cancers.⁴

RISK FACTORS^{1,6}

- Ingestion of red and processed meat.
- Hereditary syndromes—Polyposis coli and nonpolyposis syndromes (40% lifetime risk).⁴
- Inflammatory bowel disease.
- Bacteremia with *Streptococcus bovis*—Increased incidence of occult tumors.
- Following ureterosigmoidostomy procedures (5% to 10% incidence over 30 years).
- Smoking.
- Alcohol consumption.
- Family history of colon cancer in a first-degree relative.
- Obesity.

DIAGNOSIS

The diagnosis of colon cancer is sometimes made following a positive screening test [i.e., digital rectal examination, fecal occult blood test (FOBT), sigmoidoscopy, colonoscopy, or barium enema]. For patients who have symptoms and signs suggestive of colon cancer, the confirmative diagnostic test most commonly performed is colonoscopy with biopsy. Colonoscopy allows direct visualization of the lesion, examination of the entire large bowel for synchronous and metachronous lesions, and an ability to obtain tissue for histologic diagnosis.

CLINICAL FEATURES

Symptoms vary, primarily based on anatomic location, as follows:¹

- Right-sided colon tumors more commonly ulcerate, occasionally causing anemia without change in stool or bowel habits.
- Tumors in the transverse and descending colon often impede stool passage causing abdominal cramping, occasional obstruction, and rarely perforation (**Figure 64-5**).
- Tumors in the rectosigmoid region are associated more often with hematochezia, tenesmus (i.e., urgency with a feeling of incomplete evacuation), narrow caliber stool, and uncommonly, anemia.

Physical signs often appear later in the course of the disease and can include:⁴

- Weight loss and cachexia.
- Abdominal distention, discomfort, or tenderness.
- Abdominal or rectal mass.
- Ascites.
- Rectal bleeding or occult blood on rectal examination.

TYPICAL DISTRIBUTION

Colon cancers are approximately equally distributed between the right and left colon.⁷

IMAGING, ENDOSCOPY, AND WORK-UP

- Colonoscopy of the entire colon is recommended to identify additional neoplasms or polyps (**Figures 64-1** and **64-2**).
- Evaluation for metastatic disease includes:⁸
 - Local metastasis: Abdominal/pelvic CT scans.
 - Lung metastasis: Chest x-ray or chest CT.
 - Liver metastasis: MRI (pelvis), CT (abdomen and pelvis) or positron emission tomography (PET) CT scan (whole body).
 - The American College of Radiology also recommends transrectal rectum ultrasound for pretreatment staging for patients with rectal cancer and the addition of MRI of the abdomen for patients with large rectal tumors.⁹
 - Preoperative carcinoembryonic antigen (CEA)—An elevated CEA level can be used to monitor for recurrence. Pretreatment CEA (C-stage) is an independent predictor of overall mortality (60% increased risk) in patients with colon cancer.¹⁰ CEA may be elevated for reasons other than colon cancer, such as pancreatic or hepatobiliary disease; elevation does not always reflect cancer or disease recurrence.
 - At surgery, surgeons perform an examination of the liver, pelvis, hemidiaphragm, and full length of the colon for evidence of tumor spread.¹

BIOPSY

Colonic adenocarcinomas may be microscopically well-differentiated or poorly differentiated glandular structures.⁴ The addition of cytology brushings to forceps biopsies may increase the diagnostic yield, especially in the setting of obstructing tumors that cannot be traversed.¹¹

DIFFERENTIAL DIAGNOSIS

Other causes of abdominal pain in patients in this age group:

- Inflammatory bowel disease, which includes ulcerative colitis and Crohn disease (see Chapter 65, Ulcerative Colitis); symptoms include bloody diarrhea, tenesmus, passage of mucus, and cramping abdominal pain. Extraintestinal manifestations, more common in Crohn disease, include skin involvement (e.g., erythema nodosum), rheumatologic symptoms (e.g., peripheral arthritis, symmetric sacroiliitis), and ocular problems (e.g., uveitis, iritis). Diagnosis may be made on the basis of endoscopy.
- Diverticulitis—Patients present with fever, anorexia, lower left-sided abdominal pain, and diarrhea. Abdominal distention and peritonitis may be found on physical examination. Diagnosis is clinical or made on the basis of abdominal CT scan.
- Appendicitis—Initial symptoms include periumbilical or epigastric abdominal pain that over time becomes more severe and localized to the right lower quadrant. Additional symptoms include fever, nausea, vomiting, and anorexia.

Other causes of rectal bleeding:

- Infectious agents—*Salmonella*, *Shigella*, certain *Campylobacter* species, enteroinvasive *Escherichia coli*, *Clostridium difficile*, and *Entamoeba histolytica* can cause bloody, watery diarrhea, and are identified by culture test. Bacterial toxins may be identified with *C. difficile*. Additional symptoms include fever and abdominal pain and the disease is often self-limited.
- Hemorrhoids (see Chapter 66, Hemorrhoids) and fissures—Bleeding is usually bright red blood and seen in the toilet or with wiping after bowel movements. Hemorrhoids can sometimes be visible as a protruding mass often associated with pruritus, and fissures are identified as a cut or tear occurring in the anus. Hemorrhoidal pain is described as a dull ache but may be severe if thrombosed.
- Diverticula—Bleeding is usually abrupt in onset, painless, and may be massive, but often stops spontaneously. These may be seen in endoscopy or in radiographic study.
- Vascular colonic ectasias—Bleeding tends to be chronic resulting in anemia. Bleeding source may be identified during colonoscopy, but a radionuclide scan or angiography may be needed.
- Colon polyp (see Chapter 63, Colon Polyps)—Usually asymptomatic, although abdominal pain, diarrhea, or constipation can occur often with decreased stool caliber. Imaging studies often can distinguish and biopsy confirms absence of malignancy.

Other causes of intestinal obstruction include adhesions, peritonitis, inflammatory bowel disease, fecal impaction, strangulated bowels, and ileus.²

MANAGEMENT

MEDICATIONS

- Chemotherapy with fluorouracil (5-FU), irinotecan, with or without leucovorin is of marginal benefit with overall response in approximately 15% to 20% of patients.¹ For patients with stage II (Duke B) tumors (invasion into or through muscularis propria), authors of a systematic review found similar mortality rates with and without adjuvant chemotherapy.¹²
- Six months of postoperative treatment with 5-FU and leucovorin decreased recurrence for stage III (Duke C) tumors (lymph node involvement) by 40% and increased survival¹; the absolute survival benefit in one trial over leucovorin alone was approximately 12% (49% vs. 37%, respectively).¹³ A reduction in relapse rate and a modest increase in 3-year disease-free survival were also seen in patients with Duke B and C colon cancer by adding oxaliplatin to 5-FU–leucovorin; however, overall survival is only improved for a subgroup of patients.¹⁴
- For patients with metastatic disease (stage IV/Duke D), first-line multiagent chemotherapy can be considered. Three randomized controlled trials have demonstrated improved response rates, progression-free survival, and overall survival when a biologic agent (irinotecan or oxaliplatin) was combined with 5-FU–leucovorin.¹⁵

SURGERY OR OTHER TREATMENTS

- Total resection of the tumor is completed for attempted cure or for symptoms; open surgery or laparoscopic techniques may be used.¹⁶
- For superficial lesions, local excision or polypectomy with clear margins is performed; for other localized disease, wide surgical resection and reanastomosis is used.
- For patients with metastatic disease (stage IV/Duke D), treatment options include surgical resection, resection of liver metastases, palliative radiation or chemotherapy, first-line multiagent chemotherapy (see above), or participation in clinical trials.
- Total colonic resection is performed for patients with familial polyposis and multiple colonic polyps.
- For rectal carcinoma, sharp dissection is recommended (versus blunt) for rectal tumors to reduce recurrence to approximately 10%.¹ In addition, radiation therapy of the pelvis also decreases regional recurrence.¹ Postoperative treatment with 5-FU and radiation decreases recurrence for stages B2 and C tumors.¹
- Preoperative radiation therapy can be used to shrink large tumors prior to resection.

PREVENTION AND SCREENING

- Primary prevention—Increased dietary fiber (conflicting evidence) and possibly increased ingestion of fruit, vegetables, fish, and milk.^{6,17} High levels of physical activity also appear protective.^{6,17} Low-dose aspirin is also associated with a lower risk of colon cancer and death from colon cancer.¹⁸ Other medications possibly associated with a lower colon cancer risk include hormone therapy and oral contraceptives.
- Individuals who undergo at least one round of screening for colon cancer have a reduced risk of death from bowel cancer. In addition, early polyp removal by colonoscopy with polypectomy is associated with a reduced risk for colorectal cancer in the population setting.¹⁹ Of the screening tests, high-sensitivity fecal occult blood testing, flexible sigmoidoscopy (FSG) with fecal occult blood testing, and colonoscopy are recommended options.²⁰ The U.S. Preventive Services Task Force (USPSTF) recommends screening for colorectal cancer in adults, beginning at age 50 years and continuing until age 75 years.²⁰ **SOR A**
- FOBT—This test will be positive in 2% to 4% of asymptomatic patients; less than 10% will have colon cancer.¹ There is good evidence that periodic fecal occult blood testing reduces mortality from colorectal cancer; annual screening is recommended.²⁰
- FSG—There is good evidence that sigmoidoscopy in combination with fecal occult blood testing reduces mortality from colon cancer.¹¹ The ideal interval for surveillance is unknown, but the USPSTF recommends a 5-year interval of surveillance by FSG combined with a high-sensitivity FOBT every 3 years.²⁰
- Colonoscopy—There is emerging evidence that screening colonoscopy is effective in reducing colorectal cancer mortality. Population-based observational study shows a declining incidence of colon cancer and gains in life-years where colonoscopy screening programs are in place. Colonoscopy also allows inspection of the

proximal colon and early removal of polyps.^{11,21} Examples of colonoscopy pictures are shown in **Figures 64-1** to **64-3**.

- Double-contrast barium enema—This test offers an alternative means of whole-bowel examination, but is less sensitive than colonoscopy and there is no direct evidence that it is effective in reducing mortality rates. **Figures 64-4** and **64-5** display classic “apple-core deformities” of the colon from colon cancers.
- Other tests—CT colonography and stool DNA tests have been available for colorectal cancer screening. However, more research is needed to study their potential benefits and harms before widespread clinical use of these tests can be recommended as screening tools.²²
- Secondary prevention—Low-dose aspirin (81 mg) prevents adenomas in patients with previous colon cancer.²³

PROGNOSIS^{1,24}

- Duke A (T1N0M0)—Cancer limited to mucosa and submucosa; 5-year survival: 90.1%.
- Duke B1 (T2N0M0)—Cancer extends into muscularis; 5-year survival: 85%.
- Duke B2 (T3N0M0)—Cancer extends into or through serosa; 5-year survival: 70% to 80%.
- Duke C (TxN1M0)—Cancer involves regional lymph nodes; 5-year survival: 35% to 69.2%.
- Duke D (TxNxM1)—Distant metastases (i.e., lung, liver); 5-year survival: 5% to 11.7%.
- In addition to node involvement and metastases, poor outcome is associated with:¹
 - Number of regional lymph nodes involved.
 - Tumor penetration or perforation through the bowel wall.
 - Histology of poor differentiation.
 - Tumor adherence to adjacent organs.
 - Venous invasion.
 - Elevated preoperative CEA (i.e., >5 ng/mL).
 - Aneuploidy.
- Specific chromosomal deletion (e.g., allelic loss on chromosome 18q).

FOLLOW-UP

- Staging is based on tumor depth and spread and predicts survival as above.¹
- Surveillance recommendations are as follows:²⁵
 - Office visits and CEA evaluations should be performed at a minimum of 3 times per year for the first 2 years of follow-up. **SOR A**
 - There is insufficient data to recommend for or against chest x-ray (CXR) as a part of routine colorectal cancer follow-up. **SOR C**
 - Posttreatment colonoscopy should be performed at 3-year intervals. **SOR A**
 - Periodic anastomotic evaluation is recommended for patients who have undergone resection/anastomosis or local excision of rectal cancer. **SOR B**

FIGURE 64-2 Plate 2 in this series shows normal cecum. The remaining frames show a large friable mass. Biopsy confirmed adenocarcinoma. The tumor was resected and determined to be Duke stage B adenocarcinoma. Colonoscopy 3 years later was negative. (Courtesy of Michael Harper, MD.)

FIGURE 64-3 Adenocarcinoma in the cecum found on colonoscopy. (Courtesy of Marvin Derezin, MD.)

- Serum hemoglobin, hemoccult II (FOBT), and liver function tests (hepatic enzymes tests) should not be routine components of a follow-up program. **SOR A**
- For patients with progressive disease, options for further therapy must be discussed, including discontinuing therapy, intrahepatic chemotherapy (if appropriate), and experimental (i.e., phase I) therapy.

PATIENT EDUCATION

- Most recurrences occur within the first 3 to 4 years, so survival at 5 years is a good indication of cure.¹
- Surveillance for recurrence should be conducted over the first 5 years following treatment as noted above. In addition to identifying recurrence, a second tumor is found in 3% to 5% and adenomatous polyps will be found in more than 15% of patients over that period.¹

65 INFLAMMATORY BOWEL DISEASE

Mindy A. Smith, MD, MS

PATIENT STORY

A 20-year-old man presents with several days of diarrhea with a small amount of rectal bleeding with each bowel movement. This is his second episode of bloody diarrhea; the first seemed to resolve after several days and occurred several weeks ago. He has cramps that occur with each bowel movement, but feels fine between bouts of diarrhea. He has no travel history outside of the United States. He is of Jewish descent and has a cousin with Crohn disease. Colonoscopy shows mucosal friability with superficial ulceration and exudates confined to the rectosigmoid colon, and he is diagnosed with ulcerative colitis (**Figure 65-1**).

INTRODUCTION

Inflammatory bowel disease (IBD) comprises ulcerative colitis (UC) and Crohn disease. The intestinal inflammation in UC is usually confined to the mucosa and affects the rectum with or without parts or the entire colon (pancolitis) in an uninterrupted pattern. In Crohn disease, inflammation is often transmural and affects primarily the ileum and colon, often discontinuously. Crohn disease, however, can affect the entire GI tract from mouth to anus.

EPIDEMIOLOGY

- Incidence of UC in the West is 8 to 14 per 100,000 people and 6 to 15 per 100,000 people for Crohn disease.¹ Prevalence for UC and Crohn disease in North America (one of the highest rates in the world) is 37.5 to 238 per 100,000 people and 44 to 201 per 100,000 people, respectively; IBD therefore affects an estimated 1.3 million people in the United States.¹ Rates of IBD are increasing in both the West and in developing countries.¹
- Age of onset is 30 to 40 years for UC and 20 to 30 years for Crohn disease. A bimodal distribution with a second peak at ages 60 to 70 years has been reported but not confirmed.¹ Pediatric patients account for up to 20% of cases.
- Predilection for those of Jewish ancestry (especially Ashkenazi Jews) followed in order by non-Jewish whites and African Americans, Hispanics, and Asians.¹
- Inheritance (polygenic) plays a role with a concordance of 20% in monozygous twins and a risk of 10% in first-degree relatives of an incidence case.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Unknown etiology—Current theory is that colitis is an inappropriate response to microbial gut flora or a lack of regulation of intestinal

FIGURE 65-1 Ulcerative colitis in the rectosigmoid colon as viewed through the colonoscope. (Courtesy of Marvin Derezin, MD.)

immune cells in a genetically susceptible host with failure of the normal suppression of the immune response and tissue repair.^{2,3}

- Genetic regions containing nucleotide oligomerization domain 2 (NOD2; encodes an intracellular sensor of peptidoglycan), autophagy genes (regulate clearing of intracellular components like organelles), and components of the interleukin-23–type 17 helper T-cell (Th17) pathway are associated with IBD; the autophagy gene, *ATG16L1*, is associated with Crohn disease.³
- Multiple bowel pathogens (e.g., *Salmonella*, *Shigella* species, and *Campylobacter*) may trigger UC. This is supported by a large cohort study where the hazard ratio of developing IBD was 2.4 (95% confidence interval [CI], 1.7 to 3.3) in the group who experienced a bout of infectious gastroenteritis compared with the control group; the excess risk was greatest during the first year after the infective episode.⁴ People with IBD also have depletion and reduced diversity of some members of the mucosa-associated bacterial phyla, but it is not known whether this is causal or secondary to inflammation.³
- Other abnormalities found in patients with IBD include increased permeability between mucosal epithelial cells, defective regulation of intercellular junctions, infiltration into the lamina propria of innate (e.g., neutrophils) and adaptive (B and T cells) immune cells with increased production of tumor necrosis factor α and increased numbers of CD4+ T cells, dysregulation of intestinal CD4+ T-cell subgroups, and the presence of circulating antimicrobial antibodies (e.g., anti-flagellin antibodies).³ Many of the therapeutic approaches target these areas.
- Psychological factors (e.g., major life change, daily stressors) are associated with worsening symptoms.
- Patients with longstanding UC are at higher risk of developing colon dysplasia and cancer; this is believed to be a developmental sequence (see “Prognosis” below).

RISK FACTORS

- Smokers are at increased risk for Crohn disease and tend to have more severe disease, whereas former smokers and nonsmokers are at greater risk for UC.^{1,2}
- Environmental factors appear to be important triggers, especially of Crohn disease in children.¹
- Appendectomy reduces the risk of UC.¹

DIAGNOSIS

The diagnosis depends on the clinical evaluation, sigmoid appearance, histology, and a negative stool for bacteria, *Clostridium difficile* toxin, and ova and parasites.²

CLINICAL FEATURES

- Major symptoms of UC—Diarrhea, rectal bleeding, tenesmus (i.e., urgency with a feeling of incomplete evacuation), passage of mucus, and cramping abdominal pain.
- Symptoms in patients with Crohn disease depend on the location of disease; patients become symptomatic when lesions are extensive

or distal (e.g., colitis), systemic inflammatory reaction is present, or when disease is complicated by stricture, abscess, or fistula. Gross blood and mucus in the stool are less frequent and systemic symptoms, extracolonic features, pain, perineal disease, and obstruction are more common.² There is no relationship between symptoms and anatomic damage.¹

- UC is classified by severity based on the clinical picture and results of endoscopy;⁵ treatment is based on disease classification.
 - Mild: Less than 4 stools per day, with or without blood, no signs of systemic toxicity, and a normal erythrocyte sedimentation rate (ESR).
 - Moderate: More than 4 stools per day but with minimal signs of toxicity.
 - Severe: More than 6 bloody stools per day, and evidence of toxicity demonstrated by fever, tachycardia, anemia, and elevated ESR.
 - Fulminant: May have more than 10 bowel movements daily, continuous bleeding, toxicity, abdominal tenderness and distention, a blood transfusion requirement, and colonic dilation on abdominal plain films.
- Extraintestinal manifestations are present in 25% to 40% of patients with IBD, but are more common in Crohn disease than UC:^{2,6}
 - Dermatologic (2% to 34%)—Erythema nodosum (10%) that correlates with disease activity and pyogenic gangrenosum (pustule that spreads concentrically and ulcerates surrounded by violaceous borders) in 1% to 12% of patients.²
 - Rheumatologic—Peripheral arthritis (5% to 20%), spondylitis (1% to 26%, but nearly all of those positive for human leukocyte antigen B27), and symmetric sacroiliitis (<10%).
 - Ocular—Conjunctivitis, uveitis, iritis, and episcleritis (0.3% to 5%)⁶
 - Hepatobiliary—The most serious complication in this category is primary sclerosing cholangitis; although 75% of patients with this disease have UC, only 5% of those with UC and 2% of patients with Crohn disease develop it.⁶ Hepatic steatosis (fatty liver) and cholelithiasis can also occur.
 - Cardiovascular—Increased risk of deep venous thrombosis, pulmonary embolus, and stroke (because of a hypercoagulable state from thrombocytosis and gut losses of antithrombin III among other factors); endocarditis; myocarditis; and pleuropericarditis.²
 - Bone—Osteoporosis and osteomalacia from multiple causes including medications, reduced physical activity, inflammatory-mediated bone resorption, vitamin D deficiency, and calcium and magnesium malabsorption. Fracture risk in patients with IBD is 1 per 100 patient-years (40% higher than the general population).⁶
 - Renal—Nephrolithiasis, obstructive uropathy, and fistulization of the urinary tract occur in 6% to 23%.⁶
- Extraintestinal manifestations may occur prior to the diagnosis of IBD. For example, 10% to 30% of patients with IBD-related arthritis develop arthritis prior to IBD diagnosis.⁶
- Severe complications include toxic colitis (15% initially present with catastrophic illness), massive hemorrhage (1% of those with severe attacks), toxic megacolon (i.e., transverse colon diameter >5 to 6 cm) (5% of attacks; may be triggered by electrolyte abnormalities and narcotics), and bowel obstruction (caused by strictures and occurring in 10% of patients).¹

- On endoscopy in patients with Crohn disease, rectal sparing is frequent and cobblestoning of the mucosa is often seen. Small bowel involvement is seen on imaging in addition to segmental colitis and frequent strictures (**Figure 65-5**).
- Diagnosis is changed from UC to Crohn disease over time in 5% to 10% of patients.⁷

TYPICAL DISTRIBUTION

- At presentation, about a third of patients with UC have disease localized to the rectum, another third have disease present in the colorectum distal to the splenic flexure, and the remainder with disease proximal to the splenic flexure; pancolitis is present in one quarter.¹ Adults appear to always have rectal involvement, which is not the case for children. Over time (20 years), half will have pancolitis (**Figure 65-1**).⁸
- In patients with Crohn disease, lesions occur in equal proportions in the ileum, colon, or both; 10% to 15% have upper GI lesions, 20% to 30% present with perianal lesions and about half eventually develop perianal disease. Fifteen percent to 20% of patients have or have had a fistula.¹

LABORATORY TESTS

- Acute disease can result in a rise of acute phase reactants (e.g., C-reactive protein) and elevated ESR (rare in patients with just proctitis). C-reactive protein is elevated in nearly all patients with Crohn disease and in approximately half the patients with UC.⁹
- Obtain hemoglobin (to assess for anemia) and platelets (to assess for reactive thrombocytosis).
- Of the biomarkers available to detect IBD, fecal calprotectin and lactoferrin are most commonly used.⁹ The former is an indirect measure of neutrophil infiltrate in the bowel mucosa and the latter is an iron-binding protein secreted by mucosal membranes and found in neutrophil granules and serum. Although the optimal threshold value for calprotectin in detecting IBD is unknown, a study of adult patients suspected of having IBD based on clinical evaluation reported a sensitivity and specificity of the test of 93% and 96%, respectively.¹⁰ Test characteristics for lactoferrin are lower at 80% and 82%.
- Stool should be examined to rule out infectious causes including *C. difficile*; the incidence of *C. difficile* is increasing in patients with UC and is associated with a more severe course in those with IBD.¹¹

ENDOSCOPY AND IMAGING

Imaging has become more important for patients with IBD, not only for diagnosis in symptomatic patients but for early detection and treatment of inflammation in asymptomatic patients with Crohn disease and for monitoring inflammation and disease complications.¹²

- Colonoscopy with ileoscopy and mucosal biopsy should be performed in the evaluation of IBD and for differentiating UC from Crohn disease (**Figures 65-1 to 65-5**).¹³ **SOR B** It is the best test for detection of colonic inflammation.^{5,10}
- Colonoscopy can show pseudopolyps in both active UC (**Figure 65-3**) and inactive UC (**Figure 65-4**). Risks of ileocolonoscopy include perforation, limited small bowel evaluation and inability to stage penetrating disease.¹²

FIGURE 65-2 Endoscopic image showing friability and exudates over superficial ulceration in the sigmoid colon. There is edema in the cecum that, all together, indicates pan colitis. Biopsy confirmed ulcerative colitis. (Courtesy of Michael Harper, MD.)

FIGURE 65-3 Pseudopolyps in active ulcerative colitis viewed through colonoscope. (Courtesy of Marvin Derezin, MD.)

- Capsule endoscopy (CE) is a less-invasive technique for evaluating the small intestine in patients with Crohn disease and is more sensitive than radiologic and endoscopic procedures for detecting small bowel lesions and mucosal inflammation.^{12,13} **SOR B** CE should not be performed in patients with Crohn disease known or suspected to have a high-grade stricture. In that case, consider CT enterography.¹³ The major risk is retention.¹²
- In patients with initial presentation of symptomatic Crohn disease, the American College of Radiology (ACR) recommends CT enterography.¹⁴ Magnetic resonance (MR) enterography may be substituted based on institutional preference as this test appears to have similar test characteristics and avoids radiation exposure; it is the preferred test for investigating perianal disease.¹³ In addition to radiation, risks of CT enterography are related to the iodine dye and for MR enterography, image quality can be suboptimal in some patients; both tests have limited ability to detect colonic cancer.¹²
- In patients with severe disease, a plain supine film may show edematous, irregular colon margins, mucosal thickening, and toxic dilation.²

DIFFERENTIAL DIAGNOSIS

- Infections of the colon—*Salmonella*, *Shigella* species, and *Campylobacter* have a similar appearance with bloody diarrhea and abdominal pain but disease is usually self-limited and stool culture can confirm the presence of these bacteria. *C. difficile* and *Escherichia coli* can also mimic IBD.
- Numerous infectious agents including *Mycobacterium*, *Cytomegalovirus*, and protozoan parasites can mimic UC in immunocompromised patients.
- Ischemic colitis—May present with sudden onset of left lower quadrant pain, urgency to defecate, and bright red blood via rectum. It can be chronic and diffuse and should be considered in elderly patients following abdominal aorta repair or when a patient has a hypercoagulable state. Endoscopic examination often demonstrates normal rectal mucosa with a sharp transition to an area of inflammation in the descending colon or splenic flexure (**Figure 65-6**).
- Colitis associated with NSAIDs—Clinical features of diarrhea and pain, but may be complicated by bleeding, stricture, obstruction, and perforation. History is helpful and symptoms improve with withdrawal of the agent.

MANAGEMENT

MEDICATION

Treatment of acute disease in patients with UC (treatment algorithms can be found in the reference provided) is based on disease activity as follows¹⁵:

- Mild to moderate distal disease—Oral aminosalicylates (ASAs), topical mesalamine or topical steroids.⁵ **SOR A** An oral 5-ASA agent can be a prodrug (e.g., sulfasalazine, 4 to 6 g/day), a drug with a pH-dependent coating (e.g., Asacol, 2.4 to 4.8 g/day), or a slow-release agent (Pentasa, 2 to 4 g/day). Mesalamine suppositories (1 g/day) are the best way to induce remission in patients

FIGURE 65-4 Pseudopolyps in inactive ulcerative colitis viewed through colonoscope. (Courtesy of Marvin Derezin, MD.)

FIGURE 65-5 Crohn colitis with deep longitudinal ulcers and normal-appearing tissue between. The biopsies that showed normal tissue between the ulcers clinched the diagnosis for Crohn disease. Ulcerative colitis is diffuse whereas Crohn disease often skips areas as seen in this patient's colon. (Courtesy of Marvin Derezin, MD.)

with proctitis.¹⁵ Rectal suppositories or enemas should also be used to improve medication delivery when treating active distal colitis, and a combination of oral and rectal mesalamine is better than monotherapy for stopping rectal bleeding (89% vs. 46% [oral only] or 69% [rectal only]).^{5,15} **SOR A** Fifty percent to 75% of patients will show clinical improvement with 2 g/day of 5-ASA and a similar percentage will maintain remission with doses of 1.5 to 4 g/day.²

- For patients with mild to moderate active proctitis who do not respond to topical mesalamine, adding a topical corticosteroid should be considered. In patients refractory to oral ASAs or topical corticosteroids, mesalamine enemas or suppositories may still be effective.⁵ **SOR A** An oral steroid (e.g., prednisone, 40 to 60 mg/day) or infliximab (induction regimen of 5 mg/kg at weeks 1, 2, and 6) can be added for patients with mild-moderate local disease who have an inadequate response to initial therapy; the latter is often reserved for patients who do not respond to or tolerate steroids.^{5,13} **SOR C**
- Mild to moderate extensive colitis— Oral sulfasalazine (titrated to 4 to 6 g/day) or 5-ASA (up to 4.8 g/day) with or without topical therapy. **SOR A** Oral steroids are generally reserved for patients refractory to combined oral and topical ASA therapy or for those with severe symptoms requiring more prompt improvement.⁵ **SOR A** Immunomodulators (6-mercaptopurine and azathioprine) are effective for patients who do not respond to oral steroids and continue to have moderate disease.⁵ **SOR A** Patients who are steroid refractory, intolerant, or steroid-dependent despite adequate doses of a thiopurine can be considered for infliximab induction as above.⁵ **SOR A** Infliximab is contraindicated in patients with active infection, untreated latent tuberculosis, preexisting demyelinating disorder or optic neuritis, moderate to severe congestive heart failure, or current or recent malignancies.
- Severe colitis—Patients presenting with toxicity should be admitted to the hospital for IV steroids (methylprednisolone, 40 to 60 mg/day, or hydrocortisone, 200 to 300 mg/day) following hospitalization.^{5,15} **SOR C** Otherwise, treat with oral prednisone, oral ASA drugs, and topical medications with the addition of infliximab (5 mg/kg) if refractory to treatment and urgent hospitalization is not necessary.⁵ **SOR A** If patient fails to improve within 3 to 5 days, colectomy **SOR B** or IV cyclosporine **SOR A** should be considered. Antibiotics have no proven efficacy without proven infection and parenteral nutrition has not been shown to be of benefit as primary therapy for UC.⁵
- Fulminant disease—Patients should be treated as above with IV glucocorticoid and maintained without oral intake and with use of a decompression tube if small bowel ileus is present.⁵ IV cyclosporine (2 to 4 mg/kg per day) or infliximab may be considered for patients who are not improving on maximal medical therapy as above.
- Patients with Crohn disease are treated similarly except that there is limited response to mesalamine or cyclosporin and better response to nutritional therapy. A research tool called the Crohn Disease Activity Index can be used to monitor disease activity (online calculator available at <http://www.ibdjohn.com/cdai/>. Accessed October 2011).
- Mild to moderate active ileocolic Crohn disease—Budesonide (9 mg) or prednisone if distal colonic disease is present.¹⁵ Nutrition

FIGURE 65-6 Ischemic colitis in an elderly patient. (Courtesy of Marvin Derezin, MD.)

therapy is the first-line treatment for children. For patients who do not tolerate steroids or in cases where steroids are ineffective, biologic therapy with infliximab, adalimumab, or certolizumab pegol is appropriate. Methotrexate (25 mg/week) is also effective.¹⁵ Patients with weight loss or strictures may benefit from early introduction of biologic or immunomodulator therapy.¹⁵

- Severe Crohn disease in any location-Initial treatment with oral or intravenous steroids; antitumor necrosis factor therapy is reserved for patients who do not respond to initial therapy. In a single-center cohort study of 614 patients treated with infliximab, only 10.9% were not primary responders by 12 weeks, and sustained benefit was seen in 63% who received long-term treatment (mean follow-up: 55 months).¹⁶ Management also includes nutritional support and treatment of iron deficiency.
- Side effects of biologic therapy include serious infections, induction of autoimmune phenomena, and neurotoxicity.¹⁷ However, in a report of a cohort of 734 patients with IBD treated with infliximab, the most commonly observed systemic side effects were skin eruptions including psoriasiform eruptions in 20%; two patients developed tuberculosis but none of the 16 patients with positive skin tests who received prophylaxis.¹⁸

SURGERY

Surgery (total proctocolectomy with ileostomy or continence-preserving operation (i.e., ileal pouch-anal anastomosis [IPAA]) is performed in approximately half of patients with UC within 10 years of disease onset. Indications for surgery include the following^{2,5}: **SOR C**

- Intractable or fulminant disease.
- Toxic megacolon.
- Massive hemorrhage.
- Colonic obstruction or perforation.
- Colon cancer or dysplasia in flat mucosa,⁸ **SOR B** or for cancer prophylaxis.

PROGNOSIS

- In UC (**Figure 65-7**), disease flares and remissions with mucosal healing occur; remission is seen in about half of the patients within a year of onset.¹ Those who have complete clinical and endoscopic remission have a significantly decreased risk of colectomy.¹ Disease activity lessens over time with longer periods of remission. In a population study of 1575 patients with UC in Denmark, 13% had no relapse, 74% had 2 or more relapses, and 13% had active disease every year for 5 years after diagnosis.¹⁹
- The probability of colectomy over 25 years for those with UC is 20% to 30%.¹ Colectomy is not necessarily curative as pouchitis episodes occur in half of these patients by 5 years postoperatively, and in up to 10% of cases, pouchitis is chronic and often refractory to antibiotic treatment.¹
- Overall mortality is not increased for patients with UC, unless there is severe disease.¹ Although UC-related mortality from liver disease or colorectal cancer is increased, there is a decreased rate of death from pulmonary cancer and other tobacco-related diseases.¹

FIGURE 65-7 Ulcerative colitis in a 27-year-old man presenting with rectal bleeding. (Courtesy of Mark Koch, MD.)

- Recurrence postoperatively is the norm for patients with Crohn disease; only 5% have normal endoscopy at 10 years follow-up and symptoms occur about 2 to 3 years after anatomic lesions are found.²⁰ Natural progression of the disease with or without surgery is variable with spontaneous and treatment-related remissions, especially of more superficial lesions. Only approximately 10% to 15% of patients have chronic continuous disease.¹
- Most patients with Crohn disease (60% to 80%) require surgery by the time they have had the disease for 20 to 30 years (estimated at 3% to 5% per year) and greater than 10% eventually require fecal diversion, especially in patients with colorectal disease or anal stenosis.¹
- Factors associated with poor prognosis in IBD are younger age and more extensive disease. Other factors associated with poor prognosis are pouchitis and extraintestinal manifestations at surgery (IPAA) for UC and need for steroids at presentation for Crohn disease.¹
- Mortality rate for Crohn disease is slightly increased (standardized mortality ratio = 1.52); most deaths are connected to malnutrition, postoperative complications, and intestinal cancer.
- Both patients with UC and Crohn disease are at increased risk for colorectal cancer. The risk increases with duration and extent of disease and decreases following successful treatment.²¹ Colorectal cancer is rare within the first 7 years of colitis onset and increases at a rate of approximately 0.5% to 1% per year thereafter, which is likely associated with histologic disease activity.⁹ It is not clear if antiinflammatory medications reduce this risk.⁹
- Patients with cholestasis should be evaluated for primary sclerosing cholangitis and subsequent cholangiocarcinoma.⁵

FOLLOW-UP

- Support and patient education should be provided to address medication side effects, the uncertain nature of the disease, and potential complications. Discuss medication adherence in patients with apparent inadequate response to treatment.
- For maintenance of remission of mild to moderate distal disease—Mesalamine suppositories (proctitis) or enemas (distal colitis) can be dosed as infrequently as every third night.⁵ **SOR A** Patients, however, prefer oral therapy.¹⁵ Sulfasalazine, mesalamine compounds, and balsalazide are also effective in maintaining remission; the combination of oral and topical mesalamine is more effective than either one alone.⁵ **SOR A** If these fail, thiopurines and infliximab may be effective.⁵ **SOR A**
- For maintenance of remission of mild to moderate extensive colitis—Sulfasalazine, olsalazine, mesalamine (2.4 g/day), and balsalazide are effective in reducing relapses; chronic steroid use should be avoided.⁵ **SOR A** Infliximab can be used for maintenance of remission in patients who respond to infliximab induction.⁵ **SOR A** For patients who relapse despite therapy, azathioprine or 6-mercaptopurine can be used (number needed to treat to prevent 1 recurrence is 5).¹⁵
- For patients with severe colitis, long-term remission is significantly enhanced with the addition of maintenance 6-mercaptopurine.⁵ **SOR B**

- Periodic bone mineral density assessment is recommended for patients on long-term corticosteroid therapy (>3 months).²² **SOR A**
- Annual ophthalmologic examinations are recommended for patients on long-term corticosteroid therapy.²² **SOR C**
- Patients with longstanding IBD are at higher risk of developing colon dysplasia and cancer. For patients with pancolitis, the risk is 0.5% to 1% per year after 8 to 10 years of disease.^{1,2} Surveillance colonoscopy with multiple biopsies should be performed every 1 to 2 years beginning after 8 to 10 years of disease.⁵ **SOR B** There is evidence that cancers are detected at an earlier stage in patients who are undergoing surveillance.²³
- In the near future, it may be possible to monitor patients for intestinal ulcerations or thickening using noninvasive techniques (assays for C-reactive protein, fecal calprotectin and lactoferrin; videocapsule and magnetic resonance imaging) and treat them as early as possible to prevent disease progression.^{1,12} In addition, biomarkers may be useful for assessing mucosal healing, predicting relapse, and making therapeutic adjustments.⁹

PATIENT EDUCATION

- Patients should be informed about the unpredictable course of IBD and the need for frequent contact with an experienced provider for medical management, support, and surveillance.
- Smoking cessation should be stressed, particularly for patients with Crohn disease.²

66 HEMORRHOIDS

Mindy A. Smith, MD, MS

PATIENT STORY

A 42-year-old woman presents to the office with rectal pressure and occasional bright red blood on the toilet paper when wiping after bowel movements (**Figure 66-1**). She has had difficulty with constipation off and on for many years and had large hemorrhoids during her last pregnancy. Physical examination confirms the diagnosis of external hemorrhoids.

INTRODUCTION

Hemorrhoids are cushions of highly vascular structures found within the submucosa of the anal canal. They become pathologic when swollen or inflamed.

SYNONYMS

Piles.

EPIDEMIOLOGY

- More than 1 million people in Western civilization suffer from hemorrhoids each year.¹
- Estimated at 5% prevalence in the general population.²
- Approximately half of those older than age 50 years have experienced hemorrhoidal symptoms at some time.²
- More frequent in whites and in those of higher socioeconomic status.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Three hemorrhoidal cushions (comprised of subepithelial connective tissue, elastic tissue, blood vessels, and smooth muscle) surround and support distal anastomoses between the terminal branches of the superior and middle rectal arteries and the superior, middle, and inferior rectal veins.² The hemorrhoidal cushions have several functions, including maintaining fecal continence by engorging with blood and closing the anal canal and by protecting the anal sphincter during defecation.
- Hemorrhoidal tissue provides important sensory information, enabling the differentiation between solid, liquid, and gas and subsequent decision to evacuate.²
- Abnormal swelling of the anal cushions can occur from a number of causes (see “Risk Factors” below) resulting in increased pressure, with dilation and engorgement of the arteriovenous plexuses. Increased pressure can lead to stretching of the suspensory muscles, laxity of connective tissue, and eventual prolapse of rectal tissue

FIGURE 66-1 External hemorrhoid that is symptomatic. The patient had some bleeding with bowel movements. (Courtesy of Richard P. Usatine, MD.)

through the anal canal.² The engorged anal mucosa is easily traumatized, leading to rectal bleeding. Prolapse predisposes to incarceration and strangulation.

- Hemorrhoids are classified with respect to their position relative to the dentate line.
 - Internal hemorrhoids (**Figure 66-2**) develop above the dentate line and are covered by columnar epithelium of anal mucosa. Internal hemorrhoids lack somatic sensory innervation.
 - External hemorrhoids (**Figure 66-1**) arise distal to the dentate line. They are covered by stratified squamous epithelium and receive somatic sensory innervation from the inferior rectal nerve.
- Hemorrhoids are further classified into four stages of disease severity:^{1,2}
 - Stage I—Enlargement and bleeding.
 - Stage II—Protrusion of hemorrhoids with spontaneous reduction.
 - Stage III—Protrusion of hemorrhoids with manual reduction possible.
 - Stage IV—Irreducible protrusion of hemorrhoids usually containing both internal and external components with or without acute thrombosis or strangulation.

RISK FACTORS

- Family history of hemorrhoids.
- Personal history of constipation, diarrhea, and/or prolonged straining at stool.
- Pregnancy.
- Prolonged sitting or heavy lifting.

DIAGNOSIS

CLINICAL FEATURES

- Bleeding described as bright red blood (a result of the high blood oxygen content within the arteriovenous anastomoses) seen in the toilet or with wiping after bowel movements.
- Protrusion/mass (**Figure 66-1**).
- Pain described as a dull ache or severe if thrombosed.
- Inability to maintain personal hygiene/staining/soiling secondary to prolapse.
- Pruritus, also secondary to prolapse.
- Diagnosis is made on visual inspection and anoscopy, with and without straining:
 - Physical findings of swollen blood vessels protruding from the anus (**Figure 66-1**).
 - Excoriations may also be seen on the skin surrounding the anus.
 - A thrombosed hemorrhoid will be tender and firm and appear as a circular purplish bulge adjacent to the anal opening (**Figure 66-3**). There may be a black discoloration if there is accompanying necrosis.
 - Internal hemorrhoids may be visualized on anoscopy as swollen purple blood vessels arising above the dentate line.
- Other physical findings that may accompany hemorrhoids are redundant tissue and skin tags (**Figure 66-4**) from old thrombosed external hemorrhoids.

FIGURE 66-2 A large prolapsed internal hemorrhoid. (Courtesy of Charlie Goldberg, MD, and the Regents of the University of California.)

FIGURE 66-3 Thrombosed external hemorrhoid prior to elliptical excision and healing by secondary intention. Note how the hemorrhoid is at the typical 5 o'clock position. (Courtesy of Yu Wah, MD.)

DIFFERENTIAL DIAGNOSIS

- Rectal prolapse—Full-thickness circumferential protrusion appearing as a bluish, tender perianal mass. More common in women (six-fold higher incidence) and associated with other pelvic-floor disorders (e.g., cystocele, urinary incontinence). It can present as an anal mass with bleeding.¹
- Condyloma acuminata (see Chapter 133, Genital Warts)—Appear as flesh-colored, exophytic lesions on perianal skin. They may be flat, verrucous, or pedunculated.
- Anal tumors—Tumors in the rectosigmoid region are associated with hematochezia, tenesmus (i.e., urgency with a feeling of incomplete evacuation), and arrow-caliber stool; a firm mass may be found on rectal examination or seen outside the rectum.
- Inflammatory bowel disease (see Chapter 65, Inflammatory Bowel Disease)—Associated diarrhea, rectal bleeding, tenesmus, passage of mucus, and cramping abdominal pain.
- Signs of infection or abscess formation—Tender mass, sometimes feeling fluctuant, with overlying skin erythema (**Figure 66-5**). If cellulitis is also present, skin may have a woody, hard feel. Fistulas may also form and an opening may be seen on the buttock.
- Fissures—A cut or tear occurring in the anus that extends upwards into the anal canal. Common and occurring at all ages; fissures cause pain during bowel movements in addition to bleeding (**Figure 66-4**).

MANAGEMENT

NONPHARMACOLOGIC

- Patients with hemorrhoids should be encouraged to increase dietary fiber and/or add a fiber supplement to reduce severity and duration of symptoms. In a Cochrane review of seven small randomized controlled trials (RCTs), fiber supplements decreased symptoms (e.g., pain, itching, and bleeding) by 53% in the group receiving fiber.³ **SOR A**
- There are no data supporting use of sitz baths.

MEDICATIONS

- Short course of a topical steroid cream or suppositories, twice daily. **SOR C**
- For acute thrombosed external hemorrhoids, a small RCT of 98 patients treated nonsurgically found improved complete pain relief at 7 days with a combination of topical nifedipine 0.3% and lidocaine 1.5% compared with lidocaine alone (86% vs. 50%, respectively).⁴ Resolution at 14 days was reported for 92% versus 45.8%, respectively.
- Use stool softener and encourage adequate fluid intake if constipation is a factor. **SOR C**

PROCEDURES

- Internal hemorrhoids
 - Data are limited to retrospective studies and case series for most procedures.

FIGURE 66-4 Rectal fissure with prominent skin tag. (Courtesy of Charlie Goldberg, MD, copyrighted by the University of California, San Diego.)

FIGURE 66-5 Perirectal abscess: Note surrounding erythema that extends onto the right buttock. (Courtesy of Charlie Goldberg, MD, copyrighted by the University of California, San Diego.)

- Stages I to II hemorrhoids can be treated with sclerotherapy (1 to 5 mL of sclerosing agent such as sodium tetradecol sulfate injected via a 25-gauge needle into the submucosa of the hemorrhoidal complex).¹ Sclerotherapy, however, carries a high risk of postprocedure pain (70%). Urinary retention, abscess formation, and sepsis have also been reported; the author of a review recommends that only two sites be sclerosed at one time to reduce risk.² Recurrence rates are as high as 30%.²
- Stages II and III internal hemorrhoids can be treated with rubber band ligation. Two bands are placed around the engorged tissue producing ischemia and fibrosis of the hemorrhoid.
 - In a Cochrane review of three methodologically poor trials comparing excisional hemorrhoidectomy with banding for grade III hemorrhoids, results with hemorrhoidectomy were better than banding for resolution of symptoms but were associated with increased postprocedural pain, higher complication rate, and more time off work.⁵
 - Patients on anticoagulants may be better candidates for another procedure with less bleeding risk.²
 - Success rates of 50% to 100% are reported, depending on time to follow-up; there is a recurrence rate of 68% at 4 to 5 years.²
 - Complications are uncommon (<1%) and include pain, abscess formation, urinary retention, bleeding, band slippage, and sepsis.²
- Lower stage hemorrhoids can also be treated with infrared photocoagulation (IPC), bipolar electrocautery, laser therapy, or low-voltage direct current (the latter works for higher-grade hemorrhoids). IPC is initially successful in 88% to 100% of patients.²
- External hemorrhoids
 - Based on retrospective studies, excision is the most effective treatment for thrombosed external hemorrhoids. This procedure is associated with lower recurrence rates (6.5% in one study) and faster symptom resolution.⁶ **SOR B**
 - Acutely thrombosed external hemorrhoids may also be safely excised in the office or emergency room for patients who present within 48 to 72 hours of symptom onset. A local anesthetic containing epinephrine is used followed by elliptical incision (not extending beyond the anal verge or deeper than the cutaneous layer) and excision of the thrombosed hemorrhoid and overlying skin. Simple incision and clot evacuation is inadequate therapy for complete resolution, although it may relieve pain. A pressure dressing is applied for several hours, after which time the wound is left to heal by secondary intention.
 - Intraspincteric injection of botulinum toxin provided more effective pain relief at 24-hours than saline injection for patients with thrombosed external hemorrhoids not undergoing surgery.⁷

REFERRAL FOR SURGERY

- Surgeries for hemorrhoids include open and closed excision, harmonic scalpel, LigaSure tissue-sealing device, Doppler-guided transanal hemorrhoidal ligature, and stapled hemorrhoidopexy.² The ultimate need for surgical management is uncommon (5% to 10%).² The major complication is postoperative pain that can delay work return for 2 to 4 weeks.²
- Indications for surgery include:
 - Failure of nonsurgical treatment (persistent bleeding or chronic symptoms).⁶
 - Grades III and IV hemorrhoids with severe symptoms.⁶

- Presence of other anorectal conditions (e.g., anal fissure or fistula) requiring surgery.
- Patient preference.
- Stage IV hemorrhoids can be treated with traditional excision or surgery using stapling. A Cochrane review of 12 RCTs comparing conventional hemorrhoidectomy with stapling hemorrhoidopexy in patients with grades I to III hemorrhoids found a lower long-term recurrence rate (9 out of 476 [1.9%] vs. 37 out of 479 [7.7%], respectively) in patients who had conventional hemorrhoidectomy (number needed to treat [NNT] = 17).⁸ Another metaanalysis of 14 RCTs confirmed higher rates of prolapse recurrence with stapling (odds ratio [OR]: 5.5).⁹
- Use of perianal local anesthetic infiltration provides significant postoperative pain relief.¹⁰ **SOR A**
 - Combination acetaminophen and nonsteroidal antiinflammatory agents or cyclooxygenase (COX)-2–selective inhibitors should be used when possible for pain control as opioids may be constipating. There are no data supporting any particular drug over another.⁸ **SOR B**
 - Stapled hemorrhoidectomy reduces pain compared with other surgical techniques.⁸ **SOR A**
 - Other medications that can be considered as analgesic adjuncts are laxatives and metronidazole started before surgery.⁸ **SOR A**
- Complications of surgery include transient urinary retention (up to 34%), infection (rare), bleeding (2%), fecal incontinence (if sphincter muscle damage), anal stenosis, and rectal prolapse.

PROGNOSIS

Most hemorrhoids resolve spontaneously or with medical therapy alone. The recurrence rate with nonsurgical therapy is 10% to 50% (over a 5-year period), and for surgical treatment, less than 10%.

FOLLOW-UP

- After excision of a thrombosed hemorrhoid, patient instructions should include initial bed rest for several hours, sitz baths 3 times daily, stool softeners, and topical or systemic analgesia. **SOR C** The patient should return in 48 to 72 hours for a wound check.
- Similar instructions are used for patients postoperatively with respect to bed rest (1 to 2 days), sitz baths, stool softeners, and adequate fluid intake. Pain control is discussed above.

PATIENT EDUCATION

- Patients should be counseled to avoid aggravating factors including constipation and prolonged sitting.
- Advise patients who elect rubber band ligation that complications, based on one follow-up study, include pain (at 1 week, 75% of patients were pain-free and 7% were still experiencing moderate-to-severe pain), rectal bleeding (in 65% on the day after banding, persisting in 24% at 1 week), and relatively low satisfaction (only 59% were satisfied with their experience and would undergo the procedure again).¹¹

- Advise patients who elect or are recommended for surgery about potential complications of infection, thrombosis, ulceration, and incontinence.

Strength of Recommendation (SOR)	Definition
A	Recommendation based on consistent and good-quality patient-oriented evidence.*
B	Recommendation based on inconsistent or limited-quality patient-oriented evidence.*
C	Recommendation based on consensus, usual practice, opinion, disease-oriented evidence, or case series for studies of diagnosis, treatment, prevention, or screening.*

*See Appendix A on pages 1447–1450 for further information.

67 URINARY SEDIMENT

Mindy A. Smith, MD, MS
Richard P. Usatine, MD

PATIENT STORY

A 47-year-old woman presents to the office with severe right flank pain that does not radiate. Dipstick urinalysis shows hematuria, and microscopic examination confirms the presence of many red blood cells per high-power field (**Figure 67-1**). There is no pyuria or bacteriuria. The physician gives her some pain medication and sends her to get a CT urogram. The CT urogram shows a stone in the right ureter and some mild hydronephrosis. Fortunately for the patient, she passes the stone when urinating after the imaging study is complete.

INTRODUCTION

Examination of the urinary sediment is a test frequently done for evaluation of patients with suspected genetic/intrinsic (e.g., systemic lupus nephritis, renal sarcoidosis, sickle cell disease, glomerulonephritis, interstitial nephritis), anatomic (e.g., arteriovenous malformation), obstructive (e.g., kidney or bladder stones, benign prostatic hypertrophy), infectious, metabolic (e.g., coagulopathy), traumatic, or neoplastic disease of the urinary tract. Potential findings of red or white blood cells, casts, bacteria, or neoplastic cells help in directing further evaluation of a patient's problem.

EPIDEMIOLOGY

- A finding of hematuria (2 to 5 red blood cells [RBCs]/high-power field [HPF]) on a single urinalysis in an asymptomatic person is common and most often a result of menses, allergy, exercise, viral illness, or mild trauma.¹
- One study of servicemen, conducted for a period of 10 years, found an incidence of 38%.¹
- In one UK population study, first episode of hematuria resulted in a noncancer or cancer diagnosis within 90 days in 17.5% of women (95% confidence interval [CI], 16.4% to 18.6%) and 18.3% of men (95% CI, 17.4% to 19.3%).²
- Persistent (>3 RBCs/HPF over 3 specimens) and significant hematuria (>100 RBCs/HPF or gross hematuria) was associated with significant lesions in 9.1% of more than 1000 patients.¹
- In a review of hematuria, approximately 5% of patients with significant microscopic hematuria (>3 RBCs/HPF on 2 of 3 properly collected specimens during a 2- to 3-week period)³ and up to 40% of patients with gross hematuria have a neoplasm.⁴
- Isolated pyuria (>2 to 10 white blood cells per high-power field [WBCs/HPF]) is uncommon, as inflammatory processes in the urinary tract are usually associated with hematuria.¹
- In a laboratory study from 88 institutions, 62.5% of urinalysis tests received a manual microscopic evaluation of the urinary sediment,

FIGURE 67-1 Red blood cells (RBCs) seen in the urine of a woman passing a kidney stone. Some of the RBCs are crenated and there is one epithelial cell visible. (Courtesy of Richard P. Usatine, MD.)

usually triggered by an abnormal urinalysis. New information was obtained 65% of the time as a result of the manual examination.⁵

ETIOLOGY AND PATHOPHYSIOLOGY

- Hematuria (**Figure 67-1**) has many causes including:¹
 - Idiopathic (increasing incidence in the young).
 - Stones.
 - Neoplasms (increasing incidence with increase in age).
 - Trauma.
 - Infection/inflammation including acute cystitis, urethritis, pyelonephritis, and prostatitis.
 - Benign prostatic hypertrophy.
 - Metabolic abnormalities, including hypercalcemia and hyperuricemia.
 - Glomerular diseases such as immunoglobulin (Ig) A nephropathy, hereditary nephritis, and thin basement membrane disease.
- Hematuria with dysmorphic RBCs or RBC casts (**Figure 67-2**) and excess protein excretion (>500 mg/dL) indicates glomerulonephritis.
- Gross hematuria suggests a postrenal source in the collecting system.
- Pyuria (**Figure 67-3**) is often the result of urinary tract infection.
 - The presence of bacteria (>10² organisms per mL or >10⁵ using a midstream urine specimen) suggests infection. A urinalysis with 10 bacteria per HPF is highly suggestive (specificity 99%) of infection (positive likelihood ratio [LR+] 85).²
 - Asymptomatic bacteriuria is found in 4% to 15% of pregnant women, usually *Escherichia coli*.
 - The presence of WBC casts (**Figure 67-4**) with bacteria indicates pyelonephritis.
- WBCs and/or WBC casts can be seen in tubulointerstitial processes like interstitial nephritis, systemic lupus erythematosus, or transplant rejection.
- Urinary casts are formed only in the distal convoluted tubule (DCT) or in the collecting duct (distal nephron).
- Hyaline casts are formed from mucoprotein secreted by the tubular epithelial cells within the nephrons. These translucent casts are the most common type of cast and can be seen in normal persons after vigorous exercise or with dehydration. Low urine flow and concentrated urine from dehydration can contribute to the formation of hyaline casts (**Figure 67-5**).
- Granular casts are the second most common type of cast seen (**Figure 67-6**). These casts can result from the breakdown of cellular casts or the inclusion of aggregates of albumin or immunoglobulin light chains. They can be classified as fine or coarse based on the size of the inclusions. There is no diagnostic significance to the classification of fine or coarse.

RISK FACTORS

- Constipation (for urinary tract infection [UTI] in children).
- Risk factors for cancer in patients with microscopic hematuria include:⁴
 - Smoking.
 - Age older than 40 years.

FIGURE 67-2 A RBC cast caused by bleeding into the tubule from the glomerulus. These casts are seen in glomerulonephritis, IgA nephropathy, lupus nephritis, Goodpasture syndrome, and Wegener granulomatosis. RBC casts are always pathologic. (Courtesy of Agnes B. Fogo, MD, Vanderbilt University.)

FIGURE 67-3 Pyuria and bacteriuria in a woman with a urinary tract infection. A simple stain was added to the wet mount of spun urine. Although there are epithelial cells present, the culture demonstrated a true urinary tract infection (UTI) and not merely a contaminated urine. (Courtesy of Richard P. Usatine, MD.)

- Medical history of gross hematuria, urologic disease, or pelvic radiation.
- Occupational history of exposure to chemicals or dyes.
- Analgesic abuse.

DIAGNOSIS

CLINICAL FEATURES

- Other signs and symptoms of glomerular disease include various degrees of renal failure, edema, oliguria, and hypertension.
- Hematuria is often asymptomatic in patients with glomerular disease or metabolic abnormalities. Renal stones can cause pain in the ipsilateral flank and/or abdomen with radiation to the ipsilateral groin, testicle or vulva or irritative symptoms of frequency, urgency and dysuria, if located in the bladder.
- Symptoms of UTI include dysuria, nocturia, urgency, frequency, offensive odor of urine, or a combination of these; positive likelihood ratios, however, are low (1.3 to 2.3).⁶ In children, pain (abdominal pain [LR+ 6.3; 95% CI, 2.5 to 16.0] or back pain [LR+ 3.6; 95% CI, 2.1 to 6.1]), in addition to dysuria, frequency, or both (LR+ 2.2 to 2.8), and new-onset urinary incontinence (LR+ 4.6; 95% CI, 2.8 to 7.6) increased the likelihood of a UTI.⁷
- In infants, findings of previous UTI (LR+ 2.3 to 2.9), fever higher than 40°C (104°F) (LR+ 3.2 to 3.3), and suprapubic tenderness (LR+ 4.4) were the findings most useful for identifying UTI.
- Symptoms of pyelonephritis include chills and rigor, fever, nausea and vomiting, and flank pain; positive likelihood ratios are 1.5 to 2.5.
- Family history of renal failure or microscopic hematuria or history of trauma, weight loss, and changes in urine volume may be useful.

LABORATORY TESTING AND IMAGING

The work-up for persistent or significant hematuria includes the following:¹

- Urinary sediment looking for dysmorphic cells or RBC casts (**Figure 67-2**) and a 24-hour urine sample for proteinuria.
 - If positive, suspect glomerular disease and consider blood cultures, antiglomerular basement membrane (GBM) antibody, antineutrophil cytoplasmic antibody (ANCA), complement, cryoglobulins, hepatitis serologies, Venereal Disease Research Laboratory (VDRL), HIV, and antistreptolysin O; a renal biopsy may be indicated.
 - If negative and the sediment contains WBCs (**Figure 67-3**) or WBC casts (**Figure 67-4**), suspect infection and obtain a urine culture and susceptibility test if pyelonephritis is suspected; *E. coli* is the most common organism (more than 80%) in uncomplicated cystitis. WBCs seen in conjunction with many epithelial cells, particularly in women, can indicate a contaminated specimen and a new clean catch urine specimen should be obtained if possible.
 - If negative and no WBCs, obtain a hemoglobin electrophoresis, urine cytology, urinalysis (UA) from family members looking for hematuria or signs of glomerular disease, and a 24-hour urine for calcium and uric acid.

FIGURE 67-4 WBC casts seen in pyelonephritis. These can be differentiated from a clump of WBCs by their cylindrical shape and the presence of a hyaline matrix. (Courtesy of Agnes B. Fogo, MD, Vanderbilt University.)

FIGURE 67-5 Hyaline casts are translucent and proteinaceous. These are the most common casts found in the urine and can be seen in normal individuals. Concentrated urine with low flow, usually caused by dehydration, exercise, and/or diuretics, can lead to hyaline cast formation. (Courtesy of Agnes B. Fogo, MD, Vanderbilt University.)

- In all adult patients with hematuria (except for those with generalized renal parenchymal disease or young women with hemorrhagic cystitis), the American College of Radiology (ACR) recommends obtaining CT urography.⁸ In patients with generalized renal parenchymal disease and in children, ultrasound of the kidneys and bladder is recommended. For painful hematuria, a CT of the abdomen and pelvis without contrast and/or an ultrasound of the kidneys and bladder is most appropriate.⁸ For hematuria associated with trauma, obtain a CT of the abdomen and pelvis with contrast.
 - If the above is negative or high risk for cancer, perform cystoscopy.
 - If the above is positive, an open renal biopsy may be indicated.
 - If the above is negative, consider periodic follow-up (6, 12, 24, and 36 months).
- If RBC casts (**Figure 67-2**) are seen on UA in addition to proteinuria, also consider nephrotic syndrome caused by diabetes or amyloidosis.
- Note that RBC casts are fragile and are best seen in a fresh urine specimen (**Figure 67-2**).

MANAGEMENT

Treatment will depend on the underlying etiology:

- Cystitis is treated with appropriate antibiotics based on knowledge of the sensitivities of *E. coli* in your practice location (nitrofurantoin [100 mg twice daily for 5 days], trimethoprim-sulfamethoxazole [1 double-strength tablet twice-daily for 3 days], or fosfomycin [3 g single dose] are first-line agents).⁹ Symptoms usually improve within 24 to 36 hours.
- Uncomplicated pyelonephritis is treated with appropriate antibiotics as an outpatient (oral ciprofloxacin [500 mg twice daily]) for 7 days with or without an initial 400-mg intravenous dose when resistance is not known to exceed 10%).⁹ The urine should always be cultured in pyelonephritis to help guide therapy. Pregnant women may need hospitalization.
- See Chapter 68 (Kidney Stones) for management of patients with kidney stones, Chapter 71 (Renal Cell Carcinoma) for renal cell carcinoma, and Chapter 72 (Bladder Cancer) for bladder cancer.

PREVENTION AND SCREENING

- The United States Preventive Services Task Force concluded that there was insufficient evidence to assess the balance of benefits and harms of screening for bladder cancer in asymptomatic adults.¹⁰ The positive predictive value of screening is less than 10% in asymptomatic persons, including higher-risk populations.

PROVIDER RESOURCES

- *Urinalysis*—<http://library.med.utah.edu/WebPath/TUTORIAL/URINE/URINE.html>.

FIGURE 67-6 Coarse granular cast. All granular casts indicate underlying renal disease. These are nonspecific and may be seen in diverse renal conditions. (Courtesy of Agnes B. Fogo, MD, Vanderbilt University.)

68 KIDNEY STONES

Karl T. Rew, MD
Mindy A. Smith, MD, MS

PATIENT STORY

A 55-year-old woman presents with severe pain in the right flank. The pain began suddenly after supper and increased dramatically over the next hour. Urinalysis shows blood but no signs of infection. Abdominal X-ray reveals bilateral renal stones (**Figure 68-1**). A non-contrast CT scan confirms multiple bilateral renal stones, with an obstructing right distal ureteral stone and enlargement of the right kidney (**Figure 68-2**). She is subsequently found to have hyperparathyroidism, which is the cause of her multiple stones.

INTRODUCTION

A kidney stone is a solid mass that forms when minerals crystallize and collect in the urinary tract. Kidney stones can cause pain and hematuria, and may lead to complications, such as urinary tract obstruction and infection.

SYNONYMS

Kidney stone, nephrolithiasis, renal calculus, renal stone, urinary tract stone, ureterolithiasis, urolithiasis.

EPIDEMIOLOGY

- The prevalence of kidney stones is increasing in the United States.¹ More than 5% of adults have kidney stone disease, with a lifetime risk of 13% for men and 7% for women.
- Men between the ages of 40 and 60 years have the highest risk of stones; for women, the risk peaks in their 50s.²
- African Americans have a lower rate of kidney stones than white Americans.¹
- Calcium oxalate and calcium phosphate stones are the most common, occurring in 75% to 85% of patients. Struvite (magnesium ammonium phosphate) stones occur in 5% of cases. Uric acid stones occur in 5% to 10% of patients and cystine stones occur in 1% of cases. Other types of stones are less common.³
- Calcium stones are more common in men than in women (ratio 2:1), whereas struvite stones are more common in women than in men (ratio 3:1).³

ETIOLOGY AND PATHOPHYSIOLOGY

- Kidney stones form when there is supersaturation of otherwise soluble materials, usually from increased excretion of these

FIGURE 68-1 Plain X-ray of the abdomen in a 55-year-old woman showing several stones in the right kidney (red arrow) and a large left ureteral stone (white arrow) adjacent to the L2-L3 disc space.

compounds or dehydration. Urine pH is a factor in stone formation because urinary phosphate increases in alkaline urine, whereas uric acid predominates in acidic urine (pH <5.5). Higher urine citrate can decrease stone formation.

- Struvite stones are caused by infection with urea-splitting bacteria, mainly *Proteus*.
- Uric acid stones form in patients with gout or hyperuricemia caused by other causes, including myeloproliferative disorders, chemotherapy, and Lesch-Nyhan syndrome.
- Cystine stones occur in patients with an inherited defect of dibasic amino acid transport.
- Struvite, cystine, and uric acid stones can grow large, filling the renal pelvis and extending into the calyces to form staghorn calculi **Figure 68-3**.

RISK FACTORS

Infections, genetic defects, and certain drugs can increase the risk of stones, but most stones are idiopathic. Risk factors vary with type of stone, as follows:

- Calcium stones are more likely in patients who are obese⁴ and in those with diets higher in animal protein, salt, and oxalate-containing foods. Contrary to popular belief, calcium in the diet does not lead to calcium stones; in fact, calcium supplementation can prevent calcium stones by trapping oxalate in the GI tract.
- Patients with poor urinary drainage or indwelling catheters are at risk for *Proteus* urinary tract infections and struvite stones.
- Uric acid stones are associated with acidic urine, which is more common in obese patients with metabolic syndrome and insulin resistance, and in patients with chronic diarrhea.

DIAGNOSIS

CLINICAL FEATURES

- Kidney stones are often asymptomatic. Stone passage into the ureter usually causes pain and hematuria. The pain of renal colic typically begins suddenly in the ipsilateral flank or abdomen and progresses in waves, gradually increasing in intensity over the next 20 to 60 minutes. As the stone moves downward, pain may be felt in the ipsilateral groin, testis, or vulva.
- Obstructing stones cause hydronephrosis, with an associated constant dull flank pain. Stones in the bladder may cause frequency, urgency, dysuria, or recurrent urinary tract infections.

LABORATORY

- Urinalysis usually reveals microscopic hematuria and limited pyuria. Gross hematuria is possible.
- Because treatment depends on stone type, stone capture and analysis is recommended **SOR C**.
- Additional work-up is recommended for adults with recurrent stones and for children with a first stone.¹ This includes a 24-hour urine collection for pH, volume, oxalate, and citrate, with simultaneous serum tests for calcium, uric acid, electrolytes, and creatinine.

FIGURE 68-2 Noncontrast CT of the abdomen and pelvis of the same woman showing several of the stones seen in **Figure 68-1**, including a nonobstructing stone in the interpolar region of the right kidney. Because the right ureter is obstructed by a distal stone (not visible on this image), the right kidney is enlarged, with collecting system dilation and perinephric stranding. The large left proximal ureteral stone seen in this image is only partially obstructing, causing mild dilation in the left kidney collecting system. Several small stones are visible in the left kidney, and the left kidney is somewhat atrophied from chronic obstruction.

FIGURE 68-3 Bilateral staghorn calculi. (From Doherty GM. *Current Surgical Diagnosis and Treatment*; Figure 40-17, p. 1023. Copyright 2006, McGraw-Hill.)

In patients with elevated serum calcium, parathyroid hormone (PTH) should be measured.

IMAGING

- Plain abdominal X-ray will demonstrate most calcium, struvite, and cystine stones. It is recommended for patients with a prior radiopaque stone (**Figure 68-1**).
- Noncontrast helical CT (**Figures 68-4** and **68-5**) has largely replaced intravenous urography for patients with a suspected urinary tract stone because it is rapid, exposes patients to less radiation, requires no contrast, and may provide clues to diagnoses outside the urinary system. Although uric acid stones are radiolucent, they often can be detected with CT.
- Ultrasound can be used to monitor uric acid stones (typically radiolucent), to assess hydronephrosis, or to avoid using X-rays in pregnant women. Ultrasound also may provide clues to diagnoses outside the urinary system.

DIFFERENTIAL DIAGNOSIS

Other causes of flank and lower pelvic/groin pain include:

- Gynecologic conditions in women (ovarian torsion, cyst, or ectopic pregnancy)—These can often be distinguished on ultrasound. Pelvic inflammatory disease can also present with pain and is diagnosed based on clinical examination and culture.
- In men, epididymitis, prostatitis, or testicular torsion may cause pain that can be confused with kidney stones. Testicular tumors rarely cause pain. Physical examination can help differentiate these conditions.
- Cholelithiasis—Biliary colic is usually described as a steady, severe pain or ache, usually of sudden onset, located in the epigastrium or right upper quadrant (RUQ) (see Chapter 62, Gallstones). RUQ tenderness may be elicited on physical examination and ultrasound usually shows stones in the gallbladder.
- Urologic disorders including ureteropelvic junction obstruction, renal subcapsular hematoma, and renal cell carcinoma (see Chapter 71, Renal Cell Carcinoma). Imaging assists in differentiating these from kidney stones.

Abdominal pain from renal stones may be confused with:

- Colitis, appendicitis, and diverticulitis—Systemic symptoms such as fever are often seen. Symptoms of colitis include diarrhea, rectal bleeding, tenesmus (i.e., urgency with a feeling of incomplete evacuation), passage of mucus, and cramping abdominal pain (see Chapter 65, Ulcerative Colitis). GI symptoms with kidney stones are limited to nausea and vomiting from stimulation of the celiac plexus.
- Peptic ulcer disease—Epigastric pain is the hallmark, along with dyspeptic symptoms (see Chapter 59, Peptic Ulcer Disease). Stool antigen test can confirm *Helicobacter pylori* infection. Upper endoscopy is the preferred procedure for diagnosing ulcers.
- Abdominal aortic aneurysm—Peak incidence is later, usually in the sixth and seventh decades. Pain is described as severe and tearing localized to the front or back of the chest and associated with diaphoresis. Syncope and weakness may also occur.

FIGURE 68-4 An unenhanced CT performed on a 49-year-old woman with known renal stones reveals a large left staghorn calculus. The striated appearance of the left renal cortex is seen in obstruction, infection, and ischemia. (Courtesy of Michael Freckleton, MD.)

FIGURE 68-5 Noncontrast CT of the abdomen and pelvis in a 33-year-old woman showing a 3-mm obstructing stone in the distal ureter, just proximal to the ureterovesical junction.

Stones within the bladder may mimic urinary tract infection (UTI). Helpful indicators of UTI are a urine dipstick positive for nitrates (positive likelihood ratio [LR+] 26.5) and urinary sediment showing 10 or more bacteria/ high-power field (LR+ 85).

Hematuria is also seen in patients with infection (e.g., UTI, sexually transmitted infection, schistosomiasis), cancer of the bladder (see Chapter 72, Bladder Cancer) or kidney (see Chapter 71, Renal Cell Carcinoma), renal disease (glomerulonephritis, immunoglobulin [Ig] A nephropathy, lupus nephritis, hemolytic uremic syndrome), in men with prostatitis, benign prostatic hypertrophy, or prostate cancer (see Chapter 73, Prostate Cancer), or following trauma.

MANAGEMENT

NONPHARMACOLOGIC

- Adequate fluid intake is essential—2 to 3 L of water per day for most patients.⁵ **SOR B**
- Stones smaller than 5 mm are likely to pass spontaneously. About three-fourths of distal ureteral stones and about half of proximal ureteral stones will pass spontaneously. The 3-mm distal ureteral stone shown in **Figure 68-3** passed spontaneously.

MEDICATIONS

- Medical expulsive therapy with α -adrenergic blockers (such as tamsulosin) or calcium-channel blockers can increase the chance of stone passage.⁶ **SOR B**
- Effective pain control should be provided using NSAIDs and narcotics if needed. NSAIDs may need to be avoided if planning lithotripsy because of increased risk of perinephric bleeding.

COMPLEMENTARY AND ALTERNATIVE THERAPY

- For prevention of struvite stones, urine can be acidified with cranberry juice.⁵ Other supplements have been suggested as potentially protective against renal stones, but study results are conflicting.

PROCEDURES

- Stones that do not pass spontaneously or with medical expulsive therapy can be treated with lithotripsy or removed via ureteroscopy. Large stones may require percutaneous nephrolithotomy (PCNL) or open surgery.

REFERRAL

- Urgent urologic consultation is recommended for patients with stones and urosepsis, anuria, or renal failure. Urologic consultation is recommended for patients with refractory pain and nausea, extremes of age, major comorbidities, stones larger than 5 mm. **SOR C**

Indications for operative intervention:

- Infection.
- Persistent symptoms of flank pain, nausea, and vomiting.

- Failure to pass a ureteral stone after an appropriate trial of observation (2 to 4 weeks).

PREVENTION

- Foods high in oxalate should be avoided by those who form calcium oxalate stones, including rhubarb, spinach, Swiss chard, beets, apricots, figs, kiwi, many soy products, chocolate, and many nuts and seeds.
- Uric acid stones are prevented with allopurinol and a low-purine diet. High-purine foods to avoid include most fish, shellfish, and meats (especially game meats and organ meats), and protein supplements such as brewer's yeast.
- Low-calcium diets should not be used in patients with calcium stones. A low-calcium diet can increase stone formation and lower bone mineral density.

Additional treatments may be warranted based on the type of stone:

- Patients with recurrent calcium-containing stones caused by idiopathic hypercalciuria can be treated with a thiazide diuretic (reduces recurrence by 50% over 3 years). Hypokalemia should be avoided; low potassium reduces urinary citrate.
- Idiopathic stone disease can be treated with fluids and potassium citrate (2 g/day).
- For cystine stones, increasing fluid intake, alkalinizing the urine to a pH ≥ 7.5 , and a low-sodium diet are recommended. D-Penicillamine has also been used.

PROGNOSIS

- Half of the patients with a first calcium-containing stone have a recurrence within 10 years. Twenty-five percent of struvite stones recur if there was incomplete removal of the stone.
- Long-term complications are uncommon. The proportion of nephrolithiasis-related end-stage renal disease (ESRD) appears small (3.2%).

FOLLOW-UP

- A follow-up consultation to discuss kidney stone prevention is important for all patients with an initial stone. Patients started on medical therapy should be reevaluated with a 24-hour urine in 3 months. Those with a history of recurrent stones should be seen at least annually.

PATIENT EDUCATION

Maintaining water intake of at least 2 to 3 L/day (to keep urine specific gravity around 1.005) is recommended for most patients as this fluid level has been shown to reduce recurrences by half. Dietary information is available (see "Patient Resources" below).

69 HYDRONEPHROSIS

Mindy A. Smith, MD, MS

PATIENT STORY

A 74-year-old man presented with a 2-day history of severe, steady pain radiating down to the lower abdomen and left testicle. He has had urinary frequency, nocturia, hesitancy, and urinary dribbling for several years with slight worsening with time. CT scan revealed left-sided hydronephrosis (**Figure 69-1**). In this patient, an irregular mass was seen at the left ureterovesical junction compressing the bladder. Prostate cancer was found on biopsy.

INTRODUCTION

Hydronephrosis refers to distention of the renal calyces and pelvis of one or both kidneys by urine. Hydronephrosis is not a disease but a physical result of urinary blockage that may occur at the level of the kidney, ureters, bladder, or urethra. The condition may be physiologic (e.g., occurring in up to 80% of pregnant women) or pathologic.

EPIDEMIOLOGY

- The most common cause of congenital bilateral hydronephrosis is posterior urethral valves (in males). Other causes include narrowing of the ureteropelvic or ureterovesicular junction.
- Using a large European database for surveillance of congenital malformations (EUROCAT), authors found a prevalence of congenital hydronephrosis of 11.5 cases per 10,000 births; the majority (72%) was in males.¹
- Ureteropelvic junction obstruction is one of the most common congenital abnormalities of the urinary tract causing hydronephrosis, occurring in approximately 1 in 5000 to 8000 live births.²
- Authors of one systematic review reported a mean prevalence of 15% for postnatal primary vesicoureteral reflux (VUR) in children after prenatally detected hydronephrosis.³ Of the remaining cases, 53% had no postnatal anomalies and 29% had other anomalies (e.g., duplicate collecting systems; **Figure 69-2**).
- Among acquired causes in adults, pelvic tumors, renal calculi, and urethral stricture predominate.⁴ If renal colic is present, renal stone is likely present (90% in one study).⁵
- Hydronephrosis is common in pregnancy because of the compression from the enlarging uterus and functional effects of progesterone.

ETIOLOGY AND PATHOPHYSIOLOGY

- Bilateral hydronephrosis is caused by a blockage to urine flow occurring at or below the level of the bladder or urethra.
- Unilateral hydronephrosis is caused by a blockage to urine flow occurring above the level of the bladder.

FIGURE 69-1 Intravenous urogram showing left hydronephrosis and hydroureter. (From Schwartz DT, Reisdorff EJ. *Emergency Radiology*. New York: McGraw-Hill; 2000:540, Fig. 19-45. Copyright 2000.)

FIGURE 69-2 Duplicate right ureter seen with three-dimensional rendering of a CT urogram. (Courtesy Karl T. Rew, MD.)

- Multiple causes result in this condition including congenital (e.g., VUR), acquired intrinsic (e.g., calculi, inflammation, and trauma), and acquired extrinsic (e.g., pregnancy or uterine leiomyoma, retroperitoneal fibrosis). Within these groupings, obstruction may be a result of mechanical (e.g., benign prostatic hypertrophy) or functional (e.g., neurogenic bladder) defects.
- Urinary obstruction causes a rise in ureteral pressure leading to declines in glomerular filtration, tubular function (e.g., ability to transport sodium and potassium or adjust urine concentration), and renal blood flow.
- If obstruction persists, tubular atrophy and permanent nephron loss can occur.

DIAGNOSIS

- In children, the diagnosis of hydronephrosis or megaureter is often made by a routine ultrasound.
- A work-up for hydronephrosis in adults is often triggered by the discovery of azotemia (caused by impaired excretory function of sodium, urea, and water). Sudden or new onset of hypertension (because of the increased renin release with unilateral obstruction) may also trigger an investigation. A first step in the evaluation is to perform bladder catheterization. If diuresis occurs, the obstruction is below the bladder neck.

CLINICAL FEATURES

- Pain is the symptom that most commonly leads an adult patient to seek medical attention. This is caused by distention of the collecting system or renal capsule. The pain is often described as severe, steady, and radiating down to the lower abdomen, testicles, or labia. Flank pain with urination is pathognomonic for VUR.
- Disturbed excretory function or difficulty in voiding: Oliguria and anuria are symptoms of complete obstruction whereas polyuria and nocturia occur with partial obstruction (impaired concentrating ability causes osmotic diuresis).
- Fever or dysuria can occur with associated urinary tract infection (UTI).
- The physical examination may reveal distention of the kidney or bladder. Rectal exam may show an enlarged prostate or rectal/pelvic mass and pelvic examination may reveal an enlarged uterus or pelvic mass.

LABORATORY TESTING

- Urinalysis may show hematuria, pyuria, proteinuria, or bacteruria but the sediment is often normal.³
- Assess renal function (blood urea nitrogen [BUN], creatinine).
- Urodynamic testing may be indicated for patients with neurogenic bladder or other suspected bladder causes of hydronephrosis.

IMAGING

- Ultrasound imaging has a sensitivity and specificity of 90% for identifying the presence of hydronephrosis if no diuresis occurs following bladder catheterization.⁴

- If a source remains unidentified, an IV urogram (**Figures 69-1 and 69-3**) and/or CT scan (**Figure 69-4**) should be obtained to diagnose intraabdominal or retroperitoneal causes.
- One study of magnetic resonance (MR) pyelography (vs. ultrasound and urography) reported a sensitivity in detecting stones, strictures, and congenital ureteropelvic junction obstructions of 68.9%, 98.5%, and 100%, respectively, with a specificity of 98%.⁶ Accuracy regarding the level of obstruction was high (100%).
- Antegrade urography (percutaneous placement of ureteral catheter) or retrograde urography (cystoscopic placement of ureteral catheter) may be needed in patients with azotemia and poor excretory function or in those at high risk of acute renal failure from IV contrast (i.e., diabetes, multiple myeloma).
- A voiding cystourethrogram is useful in the diagnosis of VUR and bladder neck and urethral obstructions.
- For children identified in the prenatal period with hydronephrosis, the American Urologic Association (AUA) recommends a voiding cystourethrogram if there is high-grade hydronephrosis, hydroureter, or an abnormal bladder on ultrasound (late-term prenatal or postnatal), or for children who develop a UTI on observation.⁷ **SOR C**
Given the unproven value in diagnosing and treating VUR, an observational approach without screening may be taken for children with lesser grades of prenatally detected hydronephrosis (Society for Fetal Urology [SFU] grade 1 or 2).

DIFFERENTIAL DIAGNOSIS

Hydronephrosis is usually found during an investigation for symptoms such as flank pain or renal failure. Following are other causes of flank pain:

- Pyelonephritis—Fever, chills, nausea, vomiting, and diarrhea often occurring with or without symptoms of cystitis.
- Cholelithiasis—Pain is more typical in the epigastrium and right upper quadrant (biliary colic) and often nausea and vomiting occurs (see Chapter 62, Gallstones).
- Other urologic disorders include ureteropelvic junction obstruction, renal subcapsular hematoma, and renal cell carcinoma (see Chapter 71, Renal Cell Carcinoma).

Causes of unexplained renal failure in adults:

- Hypoperfusion (prerenal failure).
- Acute tubular necrosis (ATN), interstitial, glomerular, or small vessel disease (intrarenal failure).
- Hypoperfusion and ATN account for the majority of cases of acute renal failure.

MANAGEMENT

NONPHARMACOLOGIC

- Spontaneous resolution or decrease in urinary tract dilation is expected for most cases of neonatal hydronephrosis and primary megaureter diagnosed prenatally.^{8,9}

FIGURE 69-3 Large irregular calcification (arrow) representing ureterolithiasis in the left side of the pelvis in the patient in Figure 69-1. (From Schwartz DT, Reisdorff EJ. *Emergency Radiology*. New York: McGraw-Hill; 2000:539, Fig. 19-43. Copyright 2000.)

FIGURE 69-4 Right-sided hydronephrosis (arrow) seen on CT. (Courtesy Karl T. Rew, MD.)

- Functional causes may be treated by frequent voiding or catheterization (intermittent preferred).¹⁰ **SOR B**

MEDICATIONS

- Children younger than 1 year of age with VUR complicated by a history of febrile UTI or higher grades of VUR (grades III to V) should be placed on prophylactic antibiotics (sulfamethoxazole/trimethoprim or nitrofurantoin).¹¹ **SOR B**
- Adult patients with hydronephrosis, complicated by infection, should be treated with appropriate antibiotics for 3 to 4 weeks. Chronic or recurrent unilateral infections may require nephrectomy. **SOR A**
- Anticholinergic drugs (e.g., oxybutynin, tolterodine) are recommended for patients with neurogenic bladder.¹⁰ **SOR B**
- α -Adrenergic blockade in children with neurogenic bladder can also be considered, but studies are lacking.¹⁰ **SOR C**

PROCEDURES AND SURGERY

- Hydronephrosis with infection is a urologic emergency that can be treated by prompt drainage using retrograde stent insertion or percutaneous nephrostomy.¹²
- Pyeloplasty is a surgical technique for repairing an obstruction between the ureter and kidney that involves excising the obstructing segment with reanastomosis of the ureter. For children with ureteropelvic junction obstruction, three basic procedures (open pyeloplasty [OP], endopyelotomy, and laparoscopic pyeloplasty [LP]) can be used for treatment; early surgery is only needed in approximately 15% to 20% of patients.¹³ In one review of largely retrospective data, OP and LP had higher success rates than endopyelotomy (94.1% and 95.9% to 97.2% vs. 62% to 83%, respectively).¹⁴
- Treatment for VUR includes surgical repair (ureteral reimplantation or ureteroneocystostomy) or endoscopic injection of a bulking agent. Surgical repair reduces rates of pyelonephritis compared to medical treatment, but not UTI or renal scarring.¹⁵
- Stenting (conventional and metallic) is also used for bypassing ureteral obstruction to alleviate hydronephrosis.¹⁶ The American College of Radiology (ACR) recommends percutaneous antegrade ureteral stenting or percutaneous nephrostomy for afebrile non-anuric patients with acute hydronephrosis.¹⁷ In a septic patient with acute obstruction, ACR recommends urgent percutaneous nephrostomy (preferred) or urgent retrograde ureteral stenting.¹⁷
- Patients with renal failure can be treated with dialysis. **SOR A**
- Elective surgery for drainage is performed for persistent pain or progressive loss of renal function. **SOR C**

PREVENTION AND SCREENING

- The prevalence of VUR in siblings of an index case is 27.4% and in offspring 35.7%; severe reflux is identified in approximately 10% of screened patients.¹⁸ Because of the lack of randomized controlled trials of treated versus untreated screened siblings with VUR regarding health outcomes, the best screening strategy is not known. One cost analysis estimated that it would require screening 30 to 430 asymptomatic siblings 1 year of age to prevent 1 febrile UTI at a cost of \$56,000 to \$820,000 per averted episode.¹⁹

PROGNOSIS

Prognosis depends on the underlying etiology.

FOLLOW-UP

- Neonates and children with unresolved hydronephrosis or megaureter should be followed periodically with urine cultures, serum creatinine, ultrasonography, and possibly renal scan.¹¹
- Prognosis for an adult patient depends on the duration and completeness of the obstruction and associated complications like infection; complete obstruction for 1 to 2 weeks may be followed by partial return of renal function, but after 8 weeks, recovery is unlikely.⁴
- Postobstructive diuresis can cause loss of sodium, potassium, and magnesium that may require replacement in the setting of hypovolemia, hypotension, or electrolyte imbalance.

PATIENT EDUCATION

- Education regarding VUR should include a discussion of the treatment rationale, treatment approaches, and likely adherence with the care plan.¹⁰

70 POLYCYSTIC KIDNEYS

Mindy A. Smith, MD, MS

PATIENT STORY

A 43-year-old woman with newly diagnosed hypertension reports persistent bilateral flank pain. She has a family history of “kidney problems.” On urinalysis, she is noted to have microscopic hematuria. An ultrasound and abdominal CT scan show bilateral polycystic kidneys (**Figure 70-1**).

INTRODUCTION

Polycystic kidney disease (PKD) is a manifestation of a group of inherited disorders resulting in renal cyst development. In the most common form, autosomal-dominant polycystic kidney disease (ADPKD), extensive epithelial-lined cysts develop in the kidney; in some cases, abnormalities also occur in the liver, pancreas, brain, arterial blood vessels, or a combination of these sites.

EPIDEMIOLOGY

- Most common tubular disorder of the kidney, affecting 1 in 300 individuals.
- Autosomal dominant in 90% of cases, rarely as an autosomal recessive trait.¹
- Sporadic mutation in approximately 1:1000 individuals.
- ADPKD accounts for approximately 5% to 10% of cases of end-stage renal disease (ESRD) in the United States.
- Most frequently seen in the third and fourth decades of life, but can be diagnosed at any age.

ETIOLOGY AND PATHOPHYSIOLOGY

- ADPKD results from mutations in either of 2 genes that encode plasma membrane–spanning polycystin 1 (PKD1) and polycystin 2 (PKD2).² Polycystins regulate tubular and vascular development in the kidneys and other organs (liver, brain, heart, and pancreas). PKD1 and PKD2 are colocalized in primary cilia and appear to mediate Ca^{2+} signaling as a mechanosensor, essential for maintaining the differentiated state of epithelia lining tubules in the kidney and biliary tract.³ These mutations result in many abnormalities including increased proliferation and apoptosis and loss of differentiation and polarity.⁴
- Few (1% to 5%) nephrons actually develop cysts.
- Remaining renal parenchyma shows varying degrees of tubular atrophy, interstitial fibrosis, and nephrosclerosis.
- Cysts are also found in other organs such as liver (**Figure 70-2**), spleen, pancreas, and ovaries. Liver cysts are found in up to 80% of

FIGURE 70-1 Polycystic kidneys in a 43-year-old woman with hematuria. (Courtesy of Michael Freckleton, MD.)

patients with ADPKD.² There is also an increased incidence of intracranial aneurysms (5% to 12%).

- Autosomal-recessive PKD (ARPKD) is the neonatal form of PKD that is associated with enlarged kidneys and biliary dysgenesis.³ The genetic mutation in PKHD1 (polycystic kidney hepatic disease 1) involves a protein, fibrocystin, that is also localized to cilia/basal body and complexes with PKD2. This large, receptor-like protein is thought to be involved in the tubulogenesis and/or maintenance of duct-lumen architecture of epithelium.
- Rare syndromic forms of PKD include defects of the eye, central nervous system, digits, and/or neural tube.³
- A variant of PKD is glomerulocystic kidney (GCK), which refers to a kidney with greater than 5% cystic glomeruli.⁵ This condition is usually diagnosed in young patients. Although PKD-associated gene mutations have been excluded in many cases, there is a familial form of GCK presenting with cystic kidneys, hyperuricemia, and isosthenuria (concentration similar to plasma).⁵

DIAGNOSIS

Family history is a useful tool for diagnosing early ADPKD.

CLINICAL FEATURES

- Chronic flank pain as a result of the mass effect of enlarged kidneys.
- Acute pain with infection, obstruction, or hemorrhage into a cyst.
- Enlarged liver.
- Hypertension is common in adults (75%) and may be present in 10% to 30% of children.
- Kidney stones (calcium oxalate and uric acid) develop in 15% to 20% of affected individuals because of urinary stasis from distortion of the collecting system, low urine pH, and low urinary citrate.
- Nocturia may also be present from impaired renal concentrating ability.

LABORATORY TESTING

- Gross or microscopic hematuria (60%).² Obtain a urinalysis to document hematuria and a complete blood count or hemoglobin to identify anemia.

IMAGING

- Diagnosis often made with ultrasound. More than 80% of patients have cysts present by age 20 years and 100% by age 30 years. In one study, the sensitivity of ultrasound in at-risk individuals younger than age 30 years was 70% to 95%, depending on the type of PKD present.⁶ For younger patients or those with small cysts, CT scan (**Figures 70-1** and **70-2**) or MRI may be preferred.
- Cysts are commonly found in the liver (50% to 80%) (**Figure 70-2**), spleen, pancreas, and ovaries.
- The diagnosis of PKD can usually be made from ultrasound characteristics, the presence or absence of extrarenal abnormalities, and screening of parents older than 40 years of age.⁷ Age-dependent ultrasound criteria have been established for both diagnosis and disease exclusion in subjects at risk of PKD1 (the more severe disorder).⁸

FIGURE 70-2 CT scan showing multiple liver cysts and multiple cysts in both kidneys in a patient with polycystic kidney disease (Courtesy of Ves Dimov, MD, Section of Allergy, Asthma and Immunology, Department of Pediatrics, Department of Medicine, University of Chicago, ClinicalCases.org.)

- If the diagnosis is uncertain, genetic testing is available for both ADPKD and ARPKD.

DIFFERENTIAL DIAGNOSIS²

- Simple cyst—Diagnosed at any age; few cysts seen; benign features.
- Acquired cystic disease—Diagnosed in adulthood; few to many cysts; cyst development preceded by renal failure.
- Tuberous sclerosis—Diagnosed at any age; few to many renal angiomyolipomas; inherited nonmalignant tumors grow in the skin, brain/nervous system, kidneys, and heart.

MANAGEMENT

The current role of therapy in PKD is to slow the rate of progression of renal disease and minimize symptoms. However, specific treatments are on the horizon.

NONPHARMACOLOGIC

- Neither protein restriction nor tight blood pressure control decreased the decline in glomerular filtration rate (GFR) in clinical trials.^{9,10} However, in a UK population study, increasing coverage (from 7% to 46% of the population prescribed an antihypertensive agent) showed a trend towards decreasing mortality and increased intensity of antihypertensive therapy was associated with decreasing mortality in people with ADPKD.¹¹
- For episodes of gross hematuria, one author recommends bed rest, analgesics, and hydration sufficient to increase the urinary flow rate to 2 to 3 L/day; hematuria generally declines to microscopic levels in a few days.² **SOR C**

MEDICATIONS

- Control blood pressure to reduce the risk of associated cardiovascular disease. **SOR A**
- In one randomized controlled trial (RCT) (N = 46 patients with ADPKD and hypertension), no differences in renal function, urinary albumin excretion, or left ventricular mass index were detected between those treated with ramipril versus metoprolol, during 3 years of follow-up.¹² Renal function declined significantly in both groups. Angiotensin-converting enzyme inhibitors and angiotensin receptor blockers are the traditionally used agents for patients with chronic kidney disease and hypertension. **SOR A**
- Treat infection as early as possible. If pyocyst is suspected, agents that penetrate cysts such as trimethoprim-sulfamethoxazole, chloramphenicol, and ciprofloxacin are used. **SOR C**
- Future therapies focus on exploiting signaling mechanisms underlying disease pathogenesis. Experimental and observational studies suggest that the mammalian target of rapamycin (mTOR) pathway plays a critical role in cyst growth.
- A 2-year RCT of the mTOR inhibitor everolimus for patients with ADPKD (N = 46) demonstrated a slowing of the increase in total kidney volume over placebo but not the progression of renal impairment.¹³ An open-label trial (N = 100 patients with ADPKD

and early chronic kidney disease) of the mTOR inhibitor sirolimus did not show slowing of kidney growth or improved function over standard care.¹⁴

- In a RCT of octreotide (a long-acting somatostatin analog) versus placebo for patients with polycystic liver disease (some of whom had ADPKD), patients with ADPKD randomized to octreotide had a stabilization of kidney volume (versus an increase in the control group) and all patients randomized to treatment showed a reduced liver volume; there was no difference between groups in GFR.¹⁵

SURGERY AND OTHER PROCEDURES

- Cyst puncture and a sclerosing agent (i.e., ethanol) can be used in painful cysts. **SOR C**
- For painful liver enlargement, partial hepatectomy can be performed, with good outcomes reported at experienced centers.² **SOR C**
- For patients with ESRD as a result of PKD, transplantation and dialysis are options.
- In a nationwide study of 15-year outcomes following renal transplantation (N = 534 patients with ADPKD and 4779 patients without ADPKD), patients with ADPKD had better graft survival and no difference in infections, but more thromboembolic complications, more metabolic complications, and increased incidence of hypertension.¹⁶

REFERRAL

- Patients with PKD with progressive renal failure and/or ESRD should be managed by a team of providers as they often require dialysis or kidney transplantation and can develop multiple complications; other considerations include anemia management, aneurysm screening pretransplantation, and nephrectomy of the native ADPKD kidneys.¹⁷ **SOR C**
- Consider hospitalization for patients with PKD who develop acute pyelonephritis and symptomatic cyst infection.²

PROGNOSIS

- Approximately 50% of patients with ADPKD progress slowly to ESRD; kidney failure requiring renal-replacement therapy typically develops in the fourth to sixth decade of life.² Patients with ADPKD and ESRD may have more favorable outcomes compared to those with other causes of kidney failure.¹⁶
- The following are the characteristics that predict a faster rate of decline in GFR in persons with ADPKD¹⁸:
 - Greater serum creatinine (independent of GFR).
 - Greater urinary protein excretion.
 - Higher mean arterial pressure (MAP).
 - Young age.
 - Increased kidney volume (>1500 mL).²
 - Disease caused by PKD1 mutation.¹⁹
 - The presence of tubulointerstitial fibrosis.²⁰
- The ARPKD phenotype is highly variable ranging from causing neonatal death to causing minimal kidney disease presenting later in life.³
- Patients with ADPKD are also more prone to kidney stones (Chapter 68, Kidney Stones).²¹

FOLLOW-UP

- Monitor patients renal function and watch for hypertension and posttransplantation diabetes mellitus; imaging to assess the rate of increased kidney and total cyst volume may be useful in prognosis.²²
- Avoid exogenous estrogen use for women with ADPKD and liver cystic enlargement; consider limiting use in women with liver cysts.²
- For all patients with PKD with renal dysfunction, review medications to adjust for level of kidney function and avoid nephrotoxic drugs if possible. **SOR C**
- The prognosis for patients following renal transplant is fairly good. In a follow-up study of patients with autosomal dominant PKD, adult cadaveric renal transplant survival at 5 years was found to be 79%.²³
- In the absence of a family history of aneurysm, screening is not routinely recommended for asymptomatic patients; diagnostic testing should be considered in patients with ADPKD and new-onset or severe headache or other central nervous system symptoms or signs.²
- Posttransplantation, patients with ADPKD may be more prone to the development of diabetes mellitus (odds ratio 2.3, 95% confidence interval, 1.008 to 5.14).²⁴

PATIENT EDUCATION

- Explain the genetics (among patients with ADPKD disease will develop in half of their offspring) and prognosis to patients. Referral to a genetic counselor may be useful for patients considering childbearing.
- Hypertension is common and should be treated.
- Kidney dysfunction is also common and should be monitored.
- Avoid high-impact sports in which abdominal trauma may occur (e.g., boxing).²
- In otherwise healthy women with ADPKD, pregnancy is usually uncomplicated but the risks of severe hypertension and pre-eclampsia are higher than those in the general population when elevated blood pressure or renal insufficiency is present before conception.²⁵

71 RENAL CELL CARCINOMA

Mindy A. Smith, MD, MS

PATIENT STORY

A 56-year-old man with hypertension presents with a 2-week history of left-sided flank pain. Urinalysis shows microscopic hematuria and a CT scan (**Figures 71-1** and **71-2**) demonstrates a solid left renal mass. Work-up for metastatic disease was negative. A biopsy confirmed renal cell carcinoma and a radical nephrectomy was performed.

INTRODUCTION

Renal tumors are a heterogeneous group of kidney neoplasms derived from the various parts of the nephron. Each type of tumor possesses distinct genetic characteristics, histologic features, and, to some extent, clinical phenotypes that range from benign (approximately 20% of small masses) to high-grade malignancy. Ninety percent to 95% of kidney neoplasms are renal cell carcinomas (RCCs).^{1,2}

EPIDEMIOLOGY

- RCC comprises 2% to 3% of all malignant diseases in adults and is the seventh most common cancer in men and ninth most common cancer in women.²
- An estimated 60,920 cases were diagnosed and approximately 13,120 deaths occurred in 2011 from kidney and renal pelvis cancer.³ The age-adjusted incidence rate was 14.6 per 100,000 persons with a median age at diagnosis of 64 years.³
- Lifetime risk of kidney and renal pelvis cancer is 1.56% (1 in 63 people will be diagnosed during their lifetime).³ These cancers are more common in men than women (approximately 2:1).
- Approximately 2% to 3% of cases are familial (e.g., von Hippel-Lindau syndrome).²
- Metastatic disease at presentation occurs in 23% to 33%; the most common sites of distant metastases (in descending order) are lung (with or without mediastinal or hilar nodes), bone, upper abdomen (including the tumor bed, adrenal gland, contralateral kidney, and liver), brain, and other sites (e.g., skin, spleen, heart, diaphragm, gut, connective tissue, and pancreas).⁴

ETIOLOGY AND PATHOPHYSIOLOGY

The majority of renal tumors fall into the following categories:^{1,2}

- Clear cell carcinoma (from high lipid content) (60% to 80%).
- Papillary carcinoma (5% to 15%), further delineated into type 1 and the more aggressive type 2.

FIGURE 71-1 Renal cell carcinoma. CT shows solid mass in the left kidney (arrow). (Courtesy of Michael Freckleton, MD.)

FIGURE 71-2 CT with contrast in the same patient shows the solid hypodense renal cell carcinoma mass (arrow) in the left kidney and contrasting normal parenchyma. The contrast is taken up better by the remaining normal kidney tissue and the tumor becomes more visible. (Courtesy of Michael Freckleton, MD.)

- Chromophobic tumors (3% to 10%) and other rare subtypes, such as medullary, which occurs almost exclusively in patients with sickle cell trait.

RISK FACTORS^{1,2}

- Smoking (relative risk 2 to 3).
- Obesity.
- Hypertension.
- Acquired cystic disease and end-stage renal disease, including dialysis treatment.
- Family history of the disease.

DIAGNOSIS

Most presentations are incidental (identified during other tests) and, consequently, although the incidence has increased, more cancers are diagnosed at early stages.² Despite this fact, mortality rates have also increased.

CLINICAL FEATURES

- Hematuria (40%) and flank pain (40%).
- Weight loss and anemia (approximately 33%).
- Flank mass (approximately 25%).
- The classic triad of hematuria, flank pain, and flank mass occurs in 5% to 10% of patients.¹
- Other reported symptoms include night sweats, bone pain, fatigue, and sudden onset of left varicocele.
- Systemic symptoms may be caused by metastases or paraneoplastic syndromes, such as parathyroid hormone-related protein (causing hypercalcemia and renal stones), renin (causing hypertension), or erythropoietin (causing erythrocytosis).²

LABORATORY TESTING

Potentially useful studies: **SOR** **C**

- Hemoglobin (anemia).
- Liver chemistries (metastatic disease or paraneoplastic syndrome).
- Urinalysis (hematuria—gross or microscopic).
- Urine cytology (neoplastic cells).
- The National Comprehensive Cancer Network (NCCN) also suggests a metabolic panel including lactate dehydrogenase (LDH) as part of the initial work-up.⁵

IMAGING

- The work-up for indeterminate renal masses suggested by the American College of Radiology (ACR) includes either CT scan of the abdomen (**Figures 71-1 to 71-3**) (solid renal mass; signs suggestive of renal vein or caval thrombus include filling defects, enlargement of the vessel, and rim enhancement) or abdominal MRI (slightly more sensitive and tends to upgrade cystic lesions; **Figure 71-4**); either scan should be done without and with contrast.⁶

FIGURE 71-3 CT in a 70-year-old man demonstrating a heterogeneous solid mass in the midportion to lower pole of the right kidney (arrow), consistent with a primary renal cancer. The mass contains low-attenuation, likely necrotic, components and is exophytic. (Courtesy of Karl T. Rew, MD.)

FIGURE 71-4 Patient with tuberous sclerosis. MRI shows multiple angiomyolipomas in the kidneys with several lesions suspicious for renal cancer. (Courtesy of Karl T. Rew, MD.)

- An ultrasound (US) of the kidney retroperitoneal may help to clarify a mass that is probably a hyperdense cyst (the most common renal mass).
- Angiography may be used to define vascular anatomy before nephron-sparing surgery.⁶

For the purpose of staging a RCC, ACR recommends:⁶

- Multidetector CT without and with contrast.
- Chest X-ray (CXR, tumor may extend into the hilar lymph nodes) or chest CT.
- MRI if patient is unable to undergo CT with contrast.
- Bone scans and brain MRI should be reserved for patients with abnormal blood chemistries, symptoms, or large and locally aggressive or metastatic primary renal cancers.

BIOPSY

A renal biopsy is only needed on occasion based on the appearance and size of the mass; US, CT, or MRI can be used for image guidance.⁴

ACR indications for biopsy include:

- Confirming an infected cyst.
- Identifying lymphoma.
- Determining a metastasis.
- Confirming RCC in certain circumstances, including prior to ablative therapies.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of a renal mass includes:

- Simple cysts.
- Renal calculi/nephrolithiasis (see Chapter 68, Kidney Stones).
- Benign neoplasms (infrarenal hematoma, adenoma, angiomyolipoma [see **Figure 71-4**], and oncocytoma).
- Inflammatory lesions (focal bacterial nephritis, abscess, pyelonephritis, and renal tuberculosis); patients often present with systemic signs and symptoms of infection such as fever and chills.
- Other primary or metastatic tumors (neoplastic tumors involving the kidney include squamous cell carcinoma of the collecting system, transitional cell carcinomas of the renal pelvis or collecting system, sarcoma, lymphoma, nephroblastoma, and melanoma).

These can frequently be differentiated from RCC on CT scan, but biopsy may be necessary.

MANAGEMENT

Because an increasing number of tumors are identified early (tumor size <4 cm) and may be slow growing with low risk of early progression, some authors are advocating initial active surveillance.⁷

MEDICATIONS

- Investigational therapy should be considered for patients with advanced disease because chemotherapy and immunotherapy are not known to be effective.

TABLE 71-1 Stages of Renal Cell Carcinoma

Stage	Characteristics	TNM* Staging System
I	Tumor size 7 cm or smaller and found only in the kidney	T1 N0 M0
II	Tumor size larger than 7 cm and found only in the kidney	T2 N0 M0
III	Any size tumor and cancer is found only in the kidney and in 1 or more nearby lymph nodes OR Cancer is found in the main kidney blood vessels or in the fatty tissue around the kidney; cancer may be found in 1 or more nearby lymph nodes	T1 or T2 N1 M0 T3 N0 or N1 M0
IV	Tumor has spread to distant sites	T4 and N M0 Any T and N M1

*T, tumor (size and extent; T4 tumors invade beyond Gerota fascia); N, regional lymph nodes (NX unable to assess, N0 no regional lymph node metastasis, N1 metastasis in a single regional lymph node); M, metastases (M0 no distant metastasis, M1 distant metastasis).⁵

- There is some evidence that high-dose intravenous interleukin-2 results in complete remission in 7% to 8% of patients with metastatic RCC; interferon- α has also conferred minimal improvement in overall survival (3.8 months) versus control group.²
- The NCCN recommends high-dose interleukin-2 as first-line therapy for predominantly clear cell carcinoma.⁵
- Similar improvement in survival (4 to 5 months), but not cure, has been reported for targeted therapies, primarily those using antivasular epithelial growth factor agents (bevacizumab, sorafenib, sunitinib, pazopanib, tivozanib, or axitinib) or mammalian target of rapamycin (mTOR) inhibitors (temsirolimus or everolimus) usually compared to interferon- α .⁸ No placebo-controlled trial has reported a benefit on health-related quality of life.
- The European Society of Medical Oncologists recommend either sunitinib or combination of bevacizumab and interferon in good-risk and intermediate-risk patients, and temsirolimus in patients with poor-risk features and clear cell renal carcinoma.¹⁰ The NCCN recommends any of these as first-line therapy for predominantly clear cell carcinoma and enrollment in a clinical trial as the preferred strategy for non-clear cell cancers, although temsirolimus has shown some promise.⁵
- Presurgical treatment with sunitinib was reported in one case series; the drug decreased the size of primary RCC in 17 of 20 patients treated.⁹

SURGERY

- For localized disease, partial nephrectomy for small tumors and radical nephrectomy (complete removal of the kidney and Gerota fascia) for large tumors is the gold standard.^{2,10} **SOR B** For T1 tumors (**Table 71-1**), the NCCN recommends either partial (preferred) or radical nephrectomy, active surveillance for selected patients, or thermal ablation for nonsurgical candidates.⁵
- Similar to lumpectomy for localized breast cancer, partial nephrectomy for small tumors in the presence of a normal contralateral kidney appears to have similar outcomes to radical nephrectomy,

based on observational data.¹¹ Complications are uncommon and include urinary leak (3% to 5%) and hemorrhage (1%).² Advantages include better preservation of renal function, which is associated with fewer hospitalizations and lower risk of cardiac events and mortality.² In one long-term follow-up study, 5- and 10-year cancer-specific survival for nephron-sparing surgery in these cases was 98.5% and 96.7% for tumors less than 4 cm, respectively, and for imperative indications (solitary kidney) they were 89.6% and 76%, respectively. Chronic renal failure requiring dialysis was reported in 9 patients (11.2%) with a solitary kidney.¹²

- Percutaneous cryoablation or radiofrequency ablation of smaller (≤ 3.5 cm) renal masses is an alternative treatment^{13,14}; outcomes for the 2 methods appear comparable, but the procedures have not been compared in a randomized trial.¹⁵ Limitations of thermoablation include high local recurrence compared to surgery, lack of long-term data, and subsequent fibrosis that may compromise subsequent surgery if needed.
- For patients with larger tumors or local extension, radical nephrectomy offers a 40% to 60% chance of cure.² Laparoscopic approaches are used more recently, but there are no RCTs supporting this approach.¹⁶
- For patients with metastatic disease, cytoreductive nephrectomy (similar to radical nephrectomy with removal of the kidney and possibly other surrounding structures) should be considered.¹⁰ NCCN recommends nephrectomy and surgical metastasectomy for a potentially surgically resectable solitary metastatic site.⁵
- In a combined analysis of trials, survival was longer in patients with metastatic RCC randomized to radical nephrectomy followed by interferon versus interferon alone (13.6 months vs. 7.8 months, respectively).¹⁷
- Regional lymphadenectomy is controversial.
- Resection of solitary metastasis should be considered.¹⁸ In a systematic review of data on 311 surgically and 73 nonsurgically treated patients with RCC metastatic to pancreas, metastases were single in approximately 60% of both groups. Surgery appeared to improve overall survival at 2 and 5 years (80.6% and 72.6%, respectively, for the surgical group, and 41% and 14%, respectively, in unresected patients).¹⁹

FOLLOW-UP

There is no standardized follow-up regimen based on evidence. The ACR recommends a follow-up CXR and CT of the abdomen without and with contrast for patients who have been treated for RCC by radical nephrectomy or nephron-sparing surgery.⁴ The NCCN recommends chest and abdominal imaging at 2 to 6 months.⁵ An MRI can be used for patients unable to undergo CT with contrast.⁴ Most recurrences occur within 2 to 3 years after initial resection.⁴

- For patients with T1 tumors, most surveillance protocols recommend a history, physical examination, laboratory tests, and CXR be obtained every 6 to 12 months for 3 years and then yearly until year 5.⁴ Others have suggested no imaging if the tumor is less than 2.5 cm. Most protocols do not recommend surveillance with abdominal CT for patients with T1 tumors.

- For patients with T2 primary tumors, a history, physical examination, laboratory tests, and CXR is recommended annually or every 6 months for 3 years, then annually thereafter till year 5.⁴ Protocols vary widely with some not recommending abdominal CT at all, while others recommend CT at intervals ranging from annually for 3 years to once in year 2 and year 5.
- For patients with T3 or T4 primary tumors, most protocols recommend a history, physical examination, laboratory tests, and CXR be obtained every 6 months for a few years, then annually thereafter.⁴ Most also recommend abdominal CT every 3 to 6 months for 3 years after surgery and less frequently (yearly or every other year) thereafter.

PROGNOSIS

- The clinical course is highly variable and spontaneous remissions have occurred.
- In a metaanalysis of 300 cases, small tumors had an average growth rate of 0.28 cm per year.²⁰ Although follow-up for most patients was only 2 to 3 years, only 1% of these patients developed metastases.
- Among patients initially treated with partial or radical nephrectomy, local or metastatic recurrences develop in approximately 20% to 50% of them.
- Five-year survival rates are 90.8% for localized disease (stage I, confined to the kidney), 63.1% for regional disease (spread to regional lymph nodes), and 11% for metastatic disease (stage IV).³
- In one retrospective study across 5 European centers (N = 1124), prognostic factors for survival following nephrectomy for RCC on univariate analysis were TNM (tumor, nodes, metastases) stage, Fuhrman grade (based on cell morphology), symptoms, Eastern Cooperative Oncology Group performance status, tumor size, and urinary collecting system invasion.²¹
- For papillary RCC, one study found incidental detection, T classification, M classification, vascular invasion, and tumor necrosis extent were independent prognostic factors of disease-specific survival.²²
- For advanced RCC, a multivariate analysis with 246 patients found performance status 1 versus 0 (hazard ratio [HR] 1.95, $p < 0.0001$), high alkaline phosphatase (HR 1.5, $p = 0.002$), and lung metastasis only (HR 0.73, $p = 0.028$) were overall survival predictors.²³

PATIENT EDUCATION

Several prognostic algorithms, or nomograms, for RCC survival are available that may be useful in counseling patients about their probable clinical course and facilitating treatment planning.^{22,24}

72 BLADDER CANCER

Mindy A. Smith, MD, MS

PATIENT STORY

A 68-year-old man, who is a retired painter and in good health, comes to the office at the insistence of his wife. He reports that his urinary stream is smaller and he has occasional dysuria. He has no major medical problems, although he continues to smoke one pack of cigarettes per day. His urinalysis in the office shows microscopic hematuria and an irregular mass is seen in the bladder on CT scan (**Figure 72-1**). Cystoscopy shows a bladder tumor (**Figure 72-2**). Complete endoscopic resection is performed and confirms transitional cell carcinoma.

INTRODUCTION

Bladder cancer is a malignant neoplasm of the bladder, almost exclusively urothelial (transitional cell) carcinoma.

EPIDEMIOLOGY

- In 2008, there were approximately 398,329 men and 139,099 women alive in the United States who had a history of cancer of the urinary bladder.¹
- Almost 70,000 new cases (52,020 men and 17,230 women) were diagnosed and approximately 14,990 deaths occurred from bladder cancer in 2011.¹ Mean age at diagnosis is 73 years.
- The age-adjusted incidence rate (based on 2004 to 2008 data) was 21.1 per 100,000 men and women per year with a male-to-female ratio of approximately 4:1. Among men, bladder cancer is more prevalent in whites than in blacks or Hispanics (ratio of 2:1) and more prevalent in whites than in Asian/Pacific Islander or American Indian/Alaska Natives (ratio 2.4:1); for white women, incidence rates are also higher but the differences are not as great.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- Ninety percent to 95% are transitional cell cancers and the remainder are nonurothelial neoplasms, including primarily squamous cell, adenocarcinoma, and small cell carcinoma^{2,3} (**Figures 72-1 to 72-4**). Rare forms include nonepithelial neoplasms (approximately 1%), including benign tumors, such as hemangiomas or lipomas, and malignant tumors, such as angiosarcomas.³
- Transitional cells line the urinary tract from the renal pelvis to the proximal two-thirds of the urethra. Ninety percent of transitional cell tumors develop in the bladder and the others develop in the renal pelvis, ureters, or urethra.²
- Most tumors are superficial (75% to 85%).⁴ At diagnosis, approximately 51% are in situ and 35% are localized (confined to primary

FIGURE 72-1 CT with contrast reveals a bladder cancer in a 68-year-old man with hematuria. (Courtesy of Michael Freckleton, MD.)

FIGURE 72-2 Cystoscopic view of the transitional cell carcinoma in the man in **Figure 72-1**. (Courtesy of Carlos Enrique Bermejo, MD.)

site) with an additional 7% of cases having regional spread and 4% having distant metastases at diagnosis (3% unknown).²

- Multiple tumors are seen in 30% of cases.⁴
- Bladder tumor cells are also graded based on their appearance and behavior into well differentiated or low grade (grade 1), moderately well differentiated or moderate grade (grade 2), and poorly differentiated or high grade (grade 3).
- The most common sites of hematogenous spread are lung, bone, liver, and brain. Superficial lesions do not metastasize until they invade deeply and may remain indolent for years.²

RISK FACTORS

- Risk factors include smoking (odds ratio increased by 3- to 4-fold; 50% attributable risk) and exposure to pelvic radiation,⁵ the drugs phenacetin and chlornaphazine, external-beam radiation, and chronic infection, including *Schistosoma haematobium* and genitourinary tuberculosis.^{2,3}
- There is an increased risk in certain occupations, particularly those involving exposure to metals (e.g., aluminum), paint and solvents, polycyclic aromatic hydrocarbons, diesel engine emissions, aniline dyes (e.g., workers in chemical plants exposed to benzidine or *o*-toluidine),² and textiles.⁶
- An increased risk was also seen with drinking tap water (odds ratio [OR] for >2 L/day vs. ≤0.5 L/day was 1.46 [1.20 to 1.78]), with a higher risk among men (OR = 1.50, 1.21 to 1.88).⁷
- Familial cases indicate a genetic predisposition.⁸

DIAGNOSIS

CLINICAL FEATURES

- Hematuria in 80% to 90%; with microscopic hematuria approximately 2% have bladder cancer and with gross hematuria approximately 20% have bladder cancer.³
- Irritative symptoms (i.e., dysuria, frequency) are the most common presentation.
- Obstructive symptoms may occur if the tumor is located near the urethra or bladder neck.

LABORATORY

- Urine microscopy and culture to rule out bladder infection.³
- Urine cytology (high specificity [90% to 95%] but low sensitivity [23% to 60%]), CT scan of the pelvis (**Figures 72-1, 72-3, and 72-4**) or intravenous urography (IVU), and cystoscopy with biopsy (**Figure 72-2**) comprise the basic work-up.² Fluorescence cystoscopy (use of photosensitizer instilled into the bladder, can enhance detection of flat neoplastic lesions like carcinoma in situ (CIS).⁴ When CIS is found in a cystectomy specimen, 9% to 13% of patients have upper urinary tract disease.⁴
- Bladder wash cytology during cystoscopy detects most CIS.³
- A complete blood count, blood chemistry tests (including alkaline phosphatase tests), liver function tests, CT or MRI of the chest or

FIGURE 72-3 CT with contrast of a small transitional cell carcinoma of the bladder that was barely visible until the patient was scanned on side. A small bladder diverticulum is visible as well. (Courtesy of Michael Freckleton, MD.)

FIGURE 72-4 CT of locally invasive transitional cell carcinoma (arrow) of the bladder extending outside of the bladder in a 71-year-old man. The carcinoma on the patient's right is displacing the contrast toward the left side of the patient's bladder. (Courtesy of Michael Freckleton, MD.)

abdomen and a bone scan may be needed for suspected metastatic disease.^{2,3} Bone scanning may be limited to patients with bone pain and/or elevated levels of serum alkaline phosphatase.⁴

- Tumor markers such as fluorescence in situ hybridization (FISH) analysis and nuclear matrix protein (NMP) 22 identify changes in cells in the urine and are more sensitive than urine cytology for low-grade tumors with equivalent sensitivity for high-grade tumors and CIS.⁹ As specificity is low, tumor markers should not be used for diagnosis.

IMAGING

- For pretreatment staging of invasive bladder cancer, the American College of Radiology (ACR) recommends a chest X-ray (with chest CT if equivocal), CT of the abdomen and pelvis (without and with contrast) or MRI of the pelvis (especially in cases where patients are unable to undergo contrast injection), and possibly IVU; contrast-enhanced MRI is preferred over CT for local staging.⁴ **SOR C**
- The European Association of Urology (EAU) recommends multi-detector-row CT (MDCT) of the chest, abdomen, and pelvis as the optimal form of staging for patients with confirmed muscle-invasive bladder cancer, including MDCT urography for examination of the upper urinary tracts.⁹ If MDCT is not available, alternatives are excretory urography and a chest X-ray. **SOR B**
- EAU recommends renal and bladder ultrasonography, and IVU or CT prior to transurethral resection for presumed invasive bladder cancer.¹⁰ **SOR B** ACR agrees that ultrasound is useful for local tumor staging.⁴ For patients with verified invasive bladder cancer, EAU recommends either MRI with fast dynamic contrast-enhancement or MDCT with contrast enhancement for patients considered suitable for radical treatment. **SOR B**

BIOPSY

- Diagnosis is made by cystoscopy, biopsy, and histology.

DIFFERENTIAL DIAGNOSIS

- Among adult patients with microscopic hematuria, most patients have benign pathology, such as urinary tract infection, with 25% having prostate cancer and only 2% having bladder cancer.²
- Among adult patients with gross hematuria, 22% have benign cystitis and 15% to 20% have bladder cancer.²

MANAGEMENT

MEDICATIONS

Neoadjuvant cisplatin-containing combination chemotherapy (administered prior to main treatment) improves overall 5-year survival by 5% to 7% and should be considered in muscle-invasive bladder cancer irrespective of definitive treatment.^{9,11} **SOR A** It is not recommended for patients with performance status of 2 or more and impaired renal function or for primary therapy for localized bladder cancer.⁹

- The role of adjuvant chemotherapy (usually administered after surgery) for invasive bladder cancer is under debate. A Cochrane

review based on 6 small trials (N = 491) found a 25% relative reduction in the risk of death for chemotherapy compared to control patients (hazard ratio for survival 0.75; 95% CI 0.60, 0.96), suggesting a benefit for these patients.¹²

- Cisplatin-containing combination chemotherapy is first-line therapy for patients with metastatic disease and treated patients can achieve a median survival of up to 14 months.^{9,13} **SOR A**

SURGICAL

Depends on the extent (depth and grade) or spread of the disease (**Table 72-1**). Recommendations have been provided by the American Urological Association (AUA, 2007)¹³ and the EAU (2009)⁹ as given below:

- Non–muscle-invasive disease (70% to 75% of cases)—Complete endoscopic resection with or without intravesical treatment (bacille Calmette-Guérin [BCG] weekly for 6 weeks or interferon or mitomycin C). **SOR C** Low-grade tumors (Ta tumors) can be treated with resection alone or with a single postoperative dose of intravesical chemotherapy. **SOR B** In a metaanalysis of three trials, tumor recurrence was significantly lower with intravesical BCG but there was no difference in disease progression or survival.¹⁴ **SOR B** BCG treatment causes urinary frequency (71%), cystitis (67%), hematuria (23%), fever (25%),¹⁵ and, rarely, systemic granulomatous infection requiring antituberculosis treatment.
- For Ta, Tis, or T1 tumors that are initially histologically confirmed as high grade, the AUA recommends repeat resection and additional intravesical therapy (induction course of BCG followed by maintenance therapy).¹³ **SOR A** A Cochrane review based on five small trials found that immunotherapy with intravesical BCG following surgery benefits patients with medium/high risk Ta or T1 bladder cancer on delaying tumor recurrence.¹⁵ Additional Cochrane reviews found intravesical BCG more effective than intravesical epirubicin or mitomycin C in reducing tumour recurrence (the latter only for patients at high risk of recurrence)^{16,17}; mitomycin C, however, was equivalent to BCG for disease progression and survival. **SOR A**
- Persistent or recurrent superficial disease—Repeat resection with an induction course of BCG; maintenance BCG or mitomycin C is recommended or consideration of intravesical chemotherapy (valrubicin or gemcitabine). **SOR B** For treatment failure of patients with non–muscle-invasive bladder tumors, EAU recommends radical cystectomy for those with high-grade tumors and cystectomy for other patients with T1 tumors.⁹ **SOR B** Delay in cystectomy for these patients increases the risk of progression and cancer-specific death.⁹
- Recurrent high-grade T1 tumors or invasive-muscle disease (extends to muscle or lymph nodes)—Radical cystectomy and pelvic lymphadenectomy with or without systemic chemotherapy.^{2,9} **SOR C** In men, radical cystectomy includes removal of the prostate, seminal vesicles, and proximal urethra resulting in impotence. In women, the uterus, ovaries, and anterior vaginal wall are removed. Most patients receive cutaneous reservoirs (bowel or orthotopic neobladder) drained by intermittent self-catheterization.
- Chemotherapy is not used for nonurothelial cancers, such as squamous cell carcinoma or adenocarcinoma, which are primarily treated with cystectomy.²

TABLE 72-1 Bladder Cancer Categories, Stage, and 5-Year Survival Rate

Tumor Category	Stage of Tumor*	Description	5-Year Survival
Non-muscle-invasive disease			
Ta	Stage 0 (N0,M0)	Nonmuscle-invasive papillary carcinoma	90%
Tis	Stage 0 (N0,M0)	Carcinoma in situ	96.6%
T1	Stage I (N0,M0)	Tumor invading the lamina propria	
Muscle-invasive disease			
T2a	Stage II (N0,M0)	Tumor grown into inner half of muscle layer	70.7%
T2b	Stage II (N0,M0)	Tumor grown into outer half of muscle layer	
T3 [†]	Stage III (N0,M0)	Tumor through muscle layer into fatty tissue	
T4a	Stage III (N0,M0)	Tumor beyond fatty tissue into nearby organs [‡]	
T4b	Stage IV (N0,M0)	Tumor beyond into pelvic or abdominal wall [‡]	
Lymph node			
N0	Stage IV	No lymph node involvement	34.6%
N1	Stage IV	Spread to single lymph node in true pelvis	
N2	Stage IV	Spread to 2 or more lymph nodes in true pelvis	
N3	Stage IV	Spread to nodes along the common iliac artery	
Metastatic disease			
M0	Stage IV	No distant spread	5.4%
M1	Stage IV	Cancer has spread to distant sites*	

*Determined by combining the tumor category with presence or absence and number of lymph nodes involved (N), and presence or absence or distant spread (e.g., distant lymph nodes, bones, lungs, and liver).

[†]Also divided into *a* (microscopic spread into fatty tissue) and *b* (visible spread on imaging or to the eye).

[‡]Also divided into *a* (spread to prostate or uterus/vagina) and *b* (spread to pelvic or abdominal wall).

Information based on SEER data. <http://seer.cancer.gov/statfacts/html/urinb.html>. Accessed November 2011.

- Upper urinary tract recurrence—Radical nephroureterectomy. **SOR B**

OTHER THERAPY

- In a Cochrane review of three trials comparing radical radiotherapy followed by surgery (salvage cystectomy) versus radical cystectomy, overall survival was better with radical cystectomy.¹⁸ **SOR A**
- External-beam radiotherapy alone is considered an option for patients unfit for cystectomy or to stop the bleeding from a tumor when local control can't be achieved by transurethral manipulation because of extensive local tumor growth.⁹ **SOR C**

PREVENTION

- Eliminate active and passive smoking.⁹ **SOR C**

PROGNOSIS

- Most recurrences are also superficial tumors with only approximately 10% to 15% of tumors progressing to invasive disease.⁴
- Performance status, ranging from 0 (fully active) to 4 (completely disabled), and the presence or absence of visceral metastases are independent prognostic factors for survival.
- The EAU working group suggests use of a weighted scoring system to estimate recurrence and progression risk.¹⁹ Factors include number, size, category, and grade of tumors; recurrence; and

concomitant CIS. Scores range from 0 to 17 for recurrence and 0 to 23 for progression. These scores are translated into probabilities for 1-year and 5-year recurrence (15% and 31%, respectively, for a score of 0, and 61% to 78%, respectively, for a score of 10 to 17) and 1-year and 5-year progression (0.2% and 0.8%, respectively, for a score of 0, and 17% to 45%, respectively, for a score of 14 to 23).

- Risk of disease progression by tumor grade: 10% to 15% progress with grade 1 tumors, 14% to 37% with grade 2, and 33% to 64% with grade 3 tumors.²⁰
- Five-year survival rates for superficial disease are 90%; infiltrating (stage II or III), 35% to 70%; metastatic disease (stage IV), 5.4% to 20% (see **Table 72-1**).¹ Long-term disease-free survival is reported in approximately 15% of patients with nodal disease and good performance status.

FOLLOW-UP

- Recurrence rates overall are 50% with a median recurrence at 1 year (0.4 to 11 years), and 5% to 20% progress to a more advanced stage. Patients should be seen every 3 months for the first year. **SOR C** The ACR and EAU recommend stopping oncologic surveillance after 5-years of normal follow-up to be replaced by functional surveillance (e.g., renal function).^{4,9}
- For patients with high-grade Ta and T1 disease, cystoscopy, urinalysis and urine cytology are recommended every 3 months for 2 years, then every 6 months for 2 years, then annually. Imaging of the upper tract collecting system is performed every 1 to 2 years.^{2,4}

- For patients with muscle-invasive disease, laboratory tests (liver function test, creatinine clearance, electrolyte panel) in addition to a chest X-ray are recommended every 6 to 12 months with imaging of upper urinary tract, abdomen, and pelvis for recurrence every 3 to 6 months for 2 years, and then as clinically indicated.³
- For patients undergoing bladder-sparing surgery, urine cytology with or without biopsy is conducted every 3 months for 1 year, then at increasing intervals.³
- For patients undergoing cystectomy, urine cytology is conducted every 6 to 12 months, and for those undergoing cystectomy and cutaneous diversion, urethral wash cytology is recommended every 6 to 12 months.³
- For patients with cystectomy and continent orthotopic diversion, vitamin B₁₂ level should be checked annually.^{3,21}
- Bladder tumor markers from voided urine will likely improve detection of recurrence in the future, but data are still insufficient to warrant substitution of cystoscopic follow-up.^{4,22}

PATIENT EDUCATION

- The most important primary prevention for muscle-invasive bladder cancer is to eliminate active and passive smoking.
- Tumor recurrence and progression risk can be estimated from clinical and pathologic factors;⁴ this information may help in joint decision-making for primary treatment and follow-up intervals.

73 PROSTATE CANCER

Rowena A. DeSouza, MD
Melanie Ketchandji, MD

PATIENT STORY

A 65-year-old man in good health comes to the office having had a prostate specific antigen (PSA) test performed at a local health fair. He reports a normal voiding pattern and normal erectile function with no evidence of weight loss or bone pain. He has no major medical problems but does have a strong family history of prostate cancer. His PSA is 9.3 ng/mL and he chooses to have a prostate biopsy. Pathology demonstrates prostate cancer with a Gleason score of 6 (**Figure 73-1**).

INTRODUCTION

Prostate cancer is a very common cancer in men. Secondary to widespread testing, we have seen a stage migration in prostate cancer. Most patients are diagnosed with asymptomatic, clinically localized disease. Multiple factors such as Gleason score, PSA level, stage at diagnosis, and life expectancy are all factors applied to risk stratify patients associated with varying possibilities of achieving a cure. It is especially important to consider life expectancy prior to offering PSA screening.

EPIDEMIOLOGY

- Prostate cancer (**Figure 73-2**) is the leading cancer in U.S. men and the second leading cause of cancer deaths in men.¹
- It is the second most common cancer in men worldwide, with an estimated 900,000 cases and 258,000 deaths in 2008.²
- Incidence is increased with age.
- The risk of developing prostate cancer increases at age 40 years in black men and in those who have a first-degree relative with prostate cancer.
- The risk of developing prostate cancer begins to increase at age 50 years in white men who have no family history of the disease.³
- There is no peak age or modal distribution.
- The highest incidence of prostate cancer in the world is found in African American men, who have approximately a 9.8% lifetime risk of developing prostate cancer. There is accompanied by a high rate of prostate cancer mortality (**Figure 73-3**).
- The lifetime risk of prostate cancer for white men in the United States is 8%.³
- Japanese and mainland Chinese populations have the lowest rates of prostate cancer.
- Socioeconomic status appears to be unrelated to the risk of prostate cancer.

FIGURE 73-1 Microscopic image of biopsy demonstrating glands with enlarged nuclei and prominent nucleoli (hematoxylin and eosin [H&E] staining). The patient was diagnosed with prostate cancer with a Gleason score of 6. (Courtesy of E.J. Mayeaux, Jr, MD.)

FIGURE 73-2 Photograph showing adenocarcinoma on the left lower side of the specimen and bilateral benign prostatic hypertrophy toward the top. (Courtesy of E.J. Mayeaux, Jr, MD.)

Cancer sites include invasive cases only unless otherwise noted.
Mortality source: US Mortality Files, National Center for Health Statistics, CDC.
Rates are per 100,000 and are age-adjusted to the 2000 US Std Population (19 age groups - Census P25-1130). Regression lines are calculated using the Joinpoint Regression Program Version 3.5, April 2011, National Cancer Institute.

FIGURE 73-3 Age-adjusted U.S. prostate cancer mortality rates by race and ethnicity in males older than the age of 50 years. Note the higher mortality in blacks.

ETIOLOGY AND PATHOPHYSIOLOGY

- Greater than 95% of prostate cancers are adenocarcinomas.
- Histologic variants include ductal or endometrioid carcinoma, mucinous adenocarcinoma, signet cell carcinoma, small cell carcinoma, squamous and adenosquamous carcinoma, basaloid and adenoid cystic carcinoma.
- Of prostate adenocarcinomas, 70% occur in the peripheral zone, 20% in the transitional zone, and approximately 10% in the central zone (**Figure 73-4**).
- Biologic behavior is affected by histologic grade as described by the Gleason Grade and Score (**Figure 73-5**). The Gleason grade is

based on the architectural pattern of prostate cancer cells. Based upon the growth pattern and differentiation, tumors are graded from 1 to 5, with grade 1 being the most differentiated and grade 5 the least differentiated. One grade is assigned to the most common tumor pattern, and a second grade to the next most common tumor pattern. The Gleason Score is obtained by adding the two grades together and ranges from 2 to 10. A higher score indicates a greater likelihood of having non-organ-confined disease, as well as a worse outcome after treatment of localized disease.

- Patterns of spread include direct extension, hematogenous, and lymphatic.
- Lymphatic spread occurs to the hypogastric, obturator, external iliac, presacral, common iliac, and paraaortic nodes.⁴
 - Of distant metastases, 90% are osseous.
 - Visceral metastases to lung, liver, and adrenals are less commonly seen without bone involvement.⁴

RISK FACTORS

- Men who have a first-degree relative with prostate cancer have approximately a two-fold increased risk of developing prostate cancer during their lifetime.
- African American ethnicity.

DIAGNOSIS

CLINICAL FEATURES

- Prostate cancer can be associated with urinary obstructive symptoms or hematuria, but these are usually a result of other causes.

FIGURE 73-4 Diagram of prostate zones. Most prostate adenocarcinomas occur in the peripheral zone. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 73-5 Gleason scoring of prostate cancer. (From Gleason, DF. Histologic grading and clinical staging of prostatic carcinoma. In Tannenbaum M. Urologic Pathology: The Prostate. Philadelphia, PA: Lea and Febiger; 1977:171-197.)

- Rarely, bone pain can be an initial symptom, but it generally represents very advanced disease. Prior to PSA screening, men commonly presented with this symptom.
- A prostatic nodule on digital rectal examination (DRE) is not always specific for a carcinoma and can underestimate the extent of disease when it does represent a carcinoma.

LABORATORY TESTING

► PSA Screening

- PSA is a glycoprotein produced primarily by the epithelial cells that line the acini and ducts of the prostate gland.
- PSA is concentrated in prostatic tissue, and serum PSA levels are normally very low.
- Disruption of the normal prostatic architecture, such as by prostatic disease, inflammation, or trauma, allows greater amounts of PSA to enter the general circulation.⁵
- The sensitivity and specificity for PSA as a detection tool is 80% and 65%, respectively.⁵ After treatment PSA is the primary tool used to evaluate for persistent disease or metastatic disease before imaging is employed.
- The American Urological Association guidelines support screening from age 40 years old to 75 years old.⁶
- The U.S. Prevention Task Force (USPSTF) has published final recommendations against PSA-based screening for prostate cancer in asymptomatic men.⁷ They gave the guidance a D recommendation, which means there is moderate or high certainty that the service has no net benefit or that the harms outweigh the benefits, and the task force discourages use of the service. In May 2012, they concluded that many men are harmed as a result of prostate cancer screening [with PSA] and few, if any, benefit. A better test and better treatment options are needed. Until these are available, the USPSTF has recommended against screening for prostate cancer.⁷

IMAGING

► Transrectal Ultrasound

- Transrectal ultrasound (TRUS) is a sensitive but nonspecific method of detecting prostate cancer.
- A hypoechoic lesion as seen on TRUS has a 30% chance of being carcinoma.
- TRUS should not be used as a screening tool.
- The most important use of TRUS is in combination with 12-core prostate needle biopsy.³

► Bone Scan

- Radionuclide imaging is routinely used to evaluate for disseminated disease.
- Recent studies show that the likelihood of a positive bone scan in patients with a PSA value less than 10 ng/mL and no bone symptoms is 1 per 1000.⁸

▶ CT Scan and MRI

- CT scans and body-surface-coil MRI of the pelvis have poor performance characteristics for assessing metastatic disease and are not part of standard screening or staging.
- MRI with an endorectal coil is sometimes used to evaluate disease beyond the capsule, in focal therapy, and for surgical planning.

▶ Prostate Biopsy

- Performed with local anesthesia and ultrasound guidance using a spring-loaded biopsy needle to obtain 12 prostate biopsy specimens. The patient may experience significant discomfort despite the anesthetic.
- There is an estimated false negative rate of 0 to 9.3% and an estimated false positive rate of 0 to 3.8% amongst pathologists.⁹
- The percentage of positive cores, length or percentage of cancer per core can provide predictive information.
- Lower GI tract cleansing enemas and prophylactic antibiotics are routinely used.

DIFFERENTIAL DIAGNOSIS

- Prostatitis—Infection or inflammation of the prostate. This is often associated with perineal or suprapubic pain, dysuria frequency while prostate cancer is often asymptomatic.
- Benign prostatic hyperplasia—Enlarged prostate that may cause obstructive symptoms. There is no relative increase in the risk of developing prostate cancer.
- Prostatic intraepithelial neoplasia (PIN)—High-grade PIN has been noted as a precursor to prostate carcinoma.¹⁰
- Atypical glands on biopsy—The probability of detecting cancer following an atypical diagnosis is approximately 40%. Often a repeat biopsy is recommended with increased sampling of the atypical site.

MANAGEMENT

- General considerations include age, and general performance status, Gleason score, initial serum PSA, estimated tumor volume, tumor stage, and patient life expectancy.
- Options should be explained to patients so that patients can make an informed decision about which treatment best fits their values and goals.
- Active surveillance—Monitoring for disease progression over time in low-risk individuals who are likely to die with the disease rather than from the disease. Treatment is considered if significant disease progression is detected. This involves PSA testing and periodic rebiopsy.¹¹ **SOR B**
- Radical prostatectomy—Treatment of choice for patients with organ-defined disease and a life expectancy of more than 10 years. Walsh has shown that the cavernosal nerves that mediate erectile function can be identified and avoided, reducing postoperative erectile dysfunction. Rarely, significant urinary incontinence may be encountered.³

- Robotic-assisted laparoscopic prostatectomy (RALRP)—RALRP was developed to overcome the difficulties of the standard laparoscopic prostatectomy. The robotic technique allows for magnified high definition three-dimensional visualization of the operative field and wider range of motion. The majority of men opting for radical prostatectomy in the United States are having RALRP (Figure 73-6).¹² SOR B
- External beam radiation therapy (EBRT)—EBRT is also a viable treatment option for localized disease and is the choice treatment option for T3 disease. EBRT utilizes high-energy electrons to destroy cancer cells by damaging cellular DNA. Side effects can include rectal and bladder symptomatology. Short-term androgen deprivation therapy (1 to 3 years) may increase efficacy.^{13,14} SOR B
- Brachytherapy—Outpatient, ultrasound-guided, transperineal placement of ¹²⁵I or Pd radioactive seeds into the prostate. Optimal candidates have low-risk prostate cancer. Many centers utilize short-term neoadjuvant hormonal blockade given the difficulty in treated glands larger than 50 gs.¹⁵ SOR B
- Androgen ablation in combination with EBRT—There may be some synergy between the apoptotic response induced by androgen deprivation and radiotherapy. Androgen deprivation results in an average 20% decrease in prostate volume to reduce the number of target cells, and thereby improve tumor treatment. Shrinking the prostate can decrease side effects by diminishing the volume of rectum and bladder irradiated.^{13,16} SOR B
- For recurrent or advanced disease—Docetaxel (Taxotere)-based regimens can be included among the most effective treatment options for the management of patients with advanced, androgen independent prostate cancer. Results with docetaxel as a single agent and in combination regimens with estramustine (Emcyt) have provided patient benefit through an improved palliative response and improvement in quality of life as assessed through quality of life questionnaires. In addition, treatment with Docetaxal based regimens have produced objective responses such as reduced serum PSA levels by 50%, reduction in measurable disease on imaging, pain and health related quality of life. Progression-free survival was significantly increased in patients receiving docetaxel plus estramustine compared to those receiving mitoxantrone and prednisone (6.3 verses 3.2 months).^{17,18} SOR B

FIGURE 73-6 The DaVinci robot: three working arms and a camera. The robot allows for better visualization of the pelvic anatomy. (Courtesy of Intuitive Surgical.)

PREVENTION

- The Prostate Cancer Prevention Trial (PCPT) aimed to determine the prevalence of histologically proven prostate cancer among men randomized to receive daily finasteride or placebo.¹⁹
- The authors described a 24.8% reduction in the prevalence of prostate cancer among men taking finasteride; however, the cancers detected in these men were significantly higher risk cancers.¹⁹
- More recently, the Selenium and Vitamin E Cancer Prevention Trial (SELECT) found that although selenium does not prevent prostate cancer, vitamin E is associated with a significantly increased risk of prostate cancer.²⁰

PROGNOSIS

- The optimal management of patients with prostate cancer varies widely and is highly dependent upon a patient's age, overall health, and tumor risk assessment.

PATIENT EDUCATION

- Patients should be provided balanced and objective information about the risks and benefits of PSA screening, prostate biopsies, and the various options for prostate cancer treatment. This is challenging as there are conflicting opinions and interpretations of existing data. New studies are published frequently, which can change evidence-based recommendations and expert opinions. It is the physician's job to help patients navigate through the vast data and varied opinions to find a course of prevention and treatment that fits their individual needs. Although some patients will want the physician to make decisions about whether or not to get a PSA test or which cancer treatment is best, many others will appreciate balanced information so they may decide for themselves. See Patient and Provider Resources below to help inform patient–doctor discussions on these matters.
- Risk assessment calculations can be useful in discussions with patients to help them decide about screening, biopsy and treatment. Links to prostate cancer online prediction tools are listed under Provider Resources below.

SECTION 1 PREGNANCY

74 SKIN FINDINGS IN PREGNANCY

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 32-year-old G3P2 woman presents with persistent itching in her 31st week of pregnancy. The itching is constant and worse at night. Her pregnancy had been uncomplicated and she has no past history of medical problems. Many excoriations are noted and there are no blisters (**Figure 74-1**). She has no jaundice or scleral icterus. Her transaminases were greater than 300 and her total bilirubin was elevated at 2.1. Her bile salts were elevated and her hepatitis panel was negative. The ultrasound showed gallstones but no obstruction was seen. A diagnosis of “intrahepatic cholestasis of pregnancy” was made and the patient was treated with oral ursodiol (a bile salt binding agent) and topical 1% hydrocortisone cream. The bile salts and transaminases were decreased and the patient's pruritus improved but did not resolve until after delivery.¹

INTRODUCTION

Maternal skin and skin structures undergo numerous changes during pregnancy. There are two general categories of pregnancy-associated skin conditions: (a) benign skin conditions associated with normal hormonal changes of pregnancy (striae gravidarum, hyperpigmentation, hair and vascular changes), and (b) pregnancy-specific dermatoses (prurigo of pregnancy, intrahepatic cholestasis of pregnancy).

SYNONYMS

- Striae gravidarum—Stretch marks.
- Prurigo of pregnancy—Atopic eruption of pregnancy.
- Spider telangiectasias—Spider nevi or spider angiomas.
- Intrahepatic cholestasis of pregnancy—Pruritus gravidarum.

EPIDEMIOLOGY

- Almost all pregnant women develop some increase in skin pigmentation. This usually occurs in discrete areas, probably because of differences in melanocyte density.
- Striae gravidarum (stretch marks) occur in up to 90% of pregnant women by the third trimester.²
- Spider telangiectasias occur in approximately 66% of light-complected and 10% of dark-complected pregnant women,

FIGURE 74-1 Pruritus and excoriations in a patient with intrahepatic cholestasis of pregnancy. All the lesions are secondary to patient scratching. (Courtesy of Richard P. Usatine, MD.)

primarily appearing on the face, neck, and arms. The condition is most common during the first and second trimesters.³ Palmar erythema occurs in approximately two-thirds of light-complexioned and up to one-third of dark-complexioned pregnant women.²

- Hemorrhoidal, saphenous, and vulvar varicosities occur in approximately 40% of pregnant women.³
- Prurigo of pregnancy (now called atopic eruption of pregnancy) occurs with an incidence of approximately 1 in 300 to 1 in 450 pregnancies.^{4,5}
- Intrahepatic cholestasis of pregnancy occurs in approximately 1 of 146 to 1293 pregnancies in the United States.³

ETIOLOGY AND PATHOPHYSIOLOGY

- The most common skin pigmentary change is darkening of the linea alba (**Figure 74-2**), which is then called the linea nigra.⁶ It may span from the pubic symphysis to the umbilicus or all the way to the xiphoid process.
- The skin around the areola may also darken and develop a reticular type pattern. Other anatomic areas that develop hyperpigmentation are the nipples, axillae, vulva, perineum, anus, inner thighs, and neck.⁷ Darkening may also occur in nevi during pregnancy.
- As pregnancy progresses, increased eccrine activity may result in hyperhidrosis (increased sweating) and/or miliaria (“prickly heat”).⁸ Apocrine activity decreases during pregnancy but increases postpartum, so hidradenitis suppurativa improves during pregnancy but may rebound later.⁸
- Hypertrophy of sebaceous glands produces small, brown papules on the areolae (Montgomery tubercles, **Figure 74-3**) in up to half of pregnant women. They usually regress postpartum.⁸
- Stretch marks (striae distensae, striae gravidarum) begin as pink/violaceous linear patches in the sixth to seventh month of gestation and are a common cosmetic concern among pregnant women (**Figure 74-4**). They evolve into hypopigmented linear depressions. They are most common on the abdomen, breasts, and thighs, but may also arise on the lower back, buttocks, and upper arms.⁸ The cause of striae is multifactorial and includes physical factors (e.g., actual stretching of the skin) and hormonal factors adrenocortical (e.g., steroids, estrogen, and relaxin). Although striae fade postpartum, they do not completely disappear.
- Spider angiomas, arterial spiders, or spider nevi may develop, especially in whites. They occur mostly on the neck, face, upper chest, arms, and hands.⁶ Almost all regress postpartum.
- Palmar erythema may develop and may be limited to the thenar or hypothenar eminence, or may be diffuse and mottled.⁸
- Acrochordons (skin tags) may develop, enlarge, or increase on the face, neck, axillae, chest, groin, and inframammary area during the second half of pregnancy. Some may regress postpartum.⁹
- Keloids, leiomyomas, dermatofibromas, and neurofibromas may enlarge during pregnancy.⁹
- Scalp hair appears thicker during pregnancy as a result of slowing of the normal progression of hairs to the telogen (“resting”) stage, thereby creating a relative increase in anagen hair. Hair loss (telo-

FIGURE 74-2 Darkened linea alba (linea nigra) in a pregnant patient. (Courtesy of Dan Stulberg, MD.)

FIGURE 74-3 Montgomery tubercles in a pregnant woman. The brown papules on the areola are caused by hypertrophy of the normal sebaceous glands. (Courtesy of Richard P. Usatine, MD.)

gen effluvium) is common 1 to 5 months postpartum as the percentage of telogen hairs in the scalp normalizes or increases (**Figure 74-5**).⁹ Telogen effluvium resolves within 15 months postpartum, but the scalp hair may never return to prepregnancy thickness.⁹

- Hirsutism may occur on the face, arms, legs, back, and suprapubic region.⁹ Hirsutism appears to be a result of increased levels of ovarian and placental androgens. Frontoparietal hair loss (androgenic alopecia) may develop late in pregnancy but usually resolves postpartum.
- Saphenous, vulvar, and hemorrhoidal varicosities may increase in number and/or size (see Chapter 66, Hemorrhoids). This may be because of increased blood volume, increased venous pressure, or genetic predisposition. Jacquemier sign refers to venous distention in the vestibule and vagina and is associated with vulvar varicosities, which are particularly difficult to treat.⁸ Varicosities regress, at least partially, postpartum.
- Vascular type tumors may develop or enlarge during pregnancy. Pyogenic granulomas (**Figure 74-6**) (granuloma gravidarum, pregnancy tumor, pregnancy epulis) are reddish purple papules that are made up of granulation tissue (see Chapter 161, Pyogenic Granuloma). They usually begin in the first half of pregnancy and then partially regress postpartum. They most commonly appear on the gingiva, but are also common on fingers. Hemangiomas, subcutaneous hemangioendotheliomas, and glomangiomas (glomus tumors) may also occur.
- Atopic eruption of pregnancy is most common in the second or third trimester, but has been reported in all trimesters. It presents with erythematous, excoriated papules on the extensor surfaces of the limbs and trunk.^{4,5} Lesions are grouped and may appear eczematous. The eruption usually resolves in the immediate postpartum period, although it can persist for months. This should not be confused with intrahepatic cholestasis of pregnancy, which is most common in the third trimester and has no primary skin lesions (**Figure 74-4**).
- Intrahepatic cholestasis of pregnancy is usually diagnosed based on clinical history and presentation. Patients demonstrate pruritus (with or without jaundice) and no primary skin lesions. Laboratory findings consistent with cholestasis (elevated serum bile acid levels and alkaline phosphatase levels) confirms the diagnosis. Elevated bilirubin levels may or may not be found.² The etiology remains controversial. It usually resolves postpartum without specific treatment (**Figure 74-1**).

RISK FACTORS

Striae gravidarum are more common in women who are younger, non-white, have larger babies, and have higher body mass indices.² There is a familial predisposition to striae gravidarum, and women with preexisting breast or thigh striae are also more prone to this condition.¹⁰

Intrahepatic cholestasis of pregnancy is associated with a family history of the condition is common, human leukocyte antigen-A31 and -B8.³ It often recurs in subsequent pregnancies and patients have a higher risk of gallstones or a family history of gallstones. It is associated with a higher risk of premature delivery, meconium-stained amniotic fluid, and intrauterine demise.

FIGURE 74-4 Atopic eruption of pregnancy. Note the erythematous, excoriated papules on the trunk. This patient's lesions resolved about 2 weeks postpartum. She also demonstrates pink/violaceous linear patches known as striae distensae or striae gravidarum. (Courtesy of E.J. Mayeaux, Jr, MD.)

FIGURE 74-5 Telogen effluvium causing a hair loss in a young woman 1 month postpartum. The hair loss was most visible near the temples. There was no scalp inflammation or scarring. A gentle hair pull test produced four hairs in the telogen phase (with a visible bulb). Her hair returned to normal within 1 year of this visit. (Courtesy of Richard P. Usatine, MD.)

MANAGEMENT

NONPHARMACOLOGIC

- Changes such as hypertrophy of sebaceous glands, spider angiomas, palmar erythema, and varicosities usually regress postpartum and often require only symptomatic or no therapy. **SOR C**
- Varicosities may be treated with leg elevation, compression with support hose, sleeping on the left side to ease uterine pressure on the great veins, exercise, and avoidance of long periods of standing or sitting. **SOR C** (see Chapter 52, Venous Stasis).²

MEDICATIONS

- The primary treatment for pruritus in pregnancy is symptomatic. **SOR C** Topical low-potency to mid-potency corticosteroids are safe and can give symptomatic relief of itching.
- Oral antihistamines such as diphenhydramine may be used to relieve itching.² **SOR C** See Chapters 75, Pruritic Urticarial Papules and Plaques of Pregnancy and 76, Pemphigoid Gestationis for specific treatment of various pruritic diseases in pregnancy.
- Treatment of stretch marks after pregnancy with 0.1% tretinoin was reported to be beneficial but should not be used during pregnancy because of the risk of birth defects with any retinoid.¹¹ **SOR B**
- The pruritus of intrahepatic cholestasis of pregnancy may be treated with oral antihistamines. More severe cases require ursodeoxycholic acid (ursodiol [Actigall]) to relieve pruritus and improve cholestasis while reducing adverse fetal outcomes.²

SURGICAL

- Persistent, bothersome pyogenic granulomas can be excised and should be sent to pathology to rule out amelanotic melanoma (see Chapter 161, Pyogenic Granuloma). **SOR C**
- Physical lesions such as skin tags, fibromas, and angiomas may be treated by local surgical or destructive therapies. **SOR C**
- Laser treatment (585-nm and pulsed-dye laser) may be used to treat striae after pregnancy.²

COMPLEMENTARY AND ALTERNATIVE THERAPY

- Many creams, emollients, and oils containing vitamin E, cocoa butter, aloe vera lotion, and olive oil are used to attempt to prevent striae. However, there is no evidence that these treatments are effective. Limited evidence suggests that *Centella asiatica* extract plus α -tocopherol and collagen-elastic hydrolysates and tocopherol, essential fatty acids, panthenol, hyaluronic acid, elastin, and menthol may be helpful.¹² The safety of using *Centella asiatica* and other components during pregnancy are unclear.¹³

FOLLOW-UP

Conditions should be monitored during pregnancy and the patient regularly reassured. Postpartum, the patient may be followed or treated as needed.

FIGURE 74-6 Pyogenic granuloma in a pregnant woman. (Courtesy of Richard P. Usatine, MD.)

PATIENT EDUCATION

The primary aim of treatment for most skin conditions in pregnancy is to relieve symptoms, as many conditions improve or resolve postpartum. Those conditions that do not resolve can usually be safely treated postpartum when there is no risk to the pregnancy.

75 PRURITIC URTICARIAL PAPULES AND PLAQUES OF PREGNANCY

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 26-year-old pregnant woman presents at 36 weeks of gestation with a progressive itchy rash. The rash started within the abdominal striae (**Figure 75-1**) and spread to her proximal extremities. This is her first pregnancy and she has never had any rashes like this before. The itching “is maddening.” The patient is diagnosed with pruritic urticarial papules and plaques of pregnancy (PUPPP) and treated with topical steroids and oral antihistamines.

INTRODUCTION

PUPPP is a dermatosis of pregnancy characterized by a papulovesicular or urticarial eruption on the abdomen, trunk, and limbs. Other than maternal itching, PUPPP poses no increased risk of fetal or maternal morbidity.¹

SYNONYMS

- Polymorphic eruption of pregnancy (in the United Kingdom).
- Toxic erythema of pregnancy.
- Linear immunoglobulin (Ig) M dermatosis of pregnancy.
- Bourne toxemic rash of pregnancy.
- Nurse's late-onset prurigo.

EPIDEMIOLOGY

- The incidence of PUPPP is 1 out of 160 to 1 out of 300 pregnancies, making it the most common defined dermatosis of pregnancy.²
- Nulliparous patients account for more than 75% of patients with classic PUPPP.³
- PUPPP is also more common with multiple gestations, possibly because of increased abdominal distention or higher hormone levels.⁴

The rate of recurrence with subsequent pregnancies is unknown.

ETIOLOGY AND PATHOPHYSIOLOGY

- The etiology of PUPPP is unknown. PUPPP is more common with excessive stretching of the skin, possibly because of damage to connective tissue, which could result in exposure of antigens that

FIGURE 75-1 Pruritic urticarial papules and plaques of pregnancy (PUPPP) presenting as pruritic striae on the abdomen. (Courtesy of University of Texas Health Sciences Center, Division of Dermatology.)

trigger an inflammatory response.^{2,5} The disease may also represent an immunologic reaction to circulating fetal antigens.

- Onset of PUPPP is usually late in the third trimester, but may develop postpartum.^{1,3} There are case reports of first and second trimester disease.³ Pruritus may worsen after delivery, but generally resolves by 15 days postpartum. The PUPPP may resolve prior to delivery.

RISK FACTORS

- The disorder is more common with first pregnancies.⁶
- Multiple gestations.⁶
- Familial occurrences have been reported.⁴

DIAGNOSIS

CLINICAL FEATURES

PUPPP is usually diagnosed by its characteristic findings on history and physical examination. PUPPP typically presents with erythematous papules and plaques within striae with periumbilical sparing (**Figures 75-1** and **75-2**). Extreme pruritus is a hallmark of the disease and is present in all patients.¹

TYPICAL DISTRIBUTION

Abdominal striae are the most common initial site.³ The lesions usually spread to the extremities and coalesce to form urticarial plaques (**Figures 75-3** and **75-4**). The face, palms, soles, and periumbilical region are usually spared. White halos often surround the erythematous papules and are target-like, exhibiting three distinct rings or color.³

LABORATORY TESTING

There are no related laboratory abnormalities.

BIOPSY

Biopsy is not necessary when the clinical picture is classic. When the diagnosis is uncertain, perform a punch biopsy and consider immunofluorescent studies. IgM or IgA deposits may be found at the dermoepidermal junction or around blood vessels. It is preferable to biopsy a lesion off the abdomen to avoid wound-healing problems on a distended abdomen.

DIFFERENTIAL DIAGNOSIS

- Pemphigoid gestationis can be differentiated from PUPPP by its bullous lesions (see Chapter 76, Pemphigoid Gestationis).
- Erythema multiforme produces target lesions that may affect the palms and soles (see Chapter 177, Erythema Multiforme, Stevens-Johnson Syndrome, and Toxic Epidermal Necrolysis).
- Drug reactions produce various types of erythematous eruptions on the trunk and extremities. History of a new drug exposure helps to distinguish this from PUPPP (see Chapter 203, Cutaneous Drug Reactions).

FIGURE 75-2 PUPPP occurring in the first pregnancy of a 20-year-old woman during her third trimester. Note how it involves the striae of her abdomen. She also has darkening of her linea alba and umbilicus. (Courtesy of Rachel Giese, MD.)

FIGURE 75-3 Pruritic urticarial papules and plaques of pregnancy (PUPPP) on the arm. (Courtesy of Richard P. Usatine, MD.)

- Scabies infestations produce severe itching from the mite burrows that are common between the fingers and in areas of skin folds (see Chapter 143, Scabies).
- Viral exanthems may produce all types of erythematous eruptions that can be pruritic at times. The history of a fever along with upper respiratory symptoms should help to differentiate these eruptions from PUPPP (see Chapters 126, Measles and 127, Fifth Disease).

MANAGEMENT

NONPHARMACOLOGIC

- Symptom control is the main goal. Aggressive therapy is not recommended since the condition is self-limiting. **SOR C**
- Early delivery to relieve symptoms is rarely required.

General symptom relief measures such as cool baths, frequent application of emollients, wet soaks or cool packs applied to the skin provide some symptomatic relief. ⁷ **SOR C**

MEDICATIONS

- First-line therapy consists of topical steroids and oral antihistamines to alleviate symptoms. Systemic corticosteroids are occasionally required in cases of extreme pruritus. **SOR C**
- Start with a mid-potency topical corticosteroid such as 0.1% triamcinolone bid to tid. Pregnancy class B. **SOR C** High-potency, topical, corticosteroids such as fluocinonide may be applied sparingly bid to tid as severity warrants. Pregnancy class B. **SOR C**
- Diphenhydramine 25 to 50 mg PO bid to qid or similar antihistamines may be used for symptomatic relief of pruritus. Pregnancy class B. **SOR C**

In severe cases, oral prednisolone, 40 to 60 mg daily, may induce a rapid resolution of symptoms. ⁷ **SOR C**

PROGNOSIS

Apart from itching and related discomfort, the prognosis for the mother is unaffected. Recurrence of the condition in subsequent pregnancies is rare and tends to be less severe than the first episode. ⁷

Pruritus may worsen immediately after delivery, but generally resolves by 2 weeks postpartum.

FOLLOW-UP

Routine prenatal and postpartum care should be continued.

PATIENT EDUCATION

- When discussing treatment options, inform the patient that the condition is self-limited, so therapy is based on making the patient comfortable while minimizing the potential risks involved in the use of medications. ⁶

FIGURE 75-4 Pruritic urticarial papules and plaques of pregnancy (PUPPP) on the leg. (Courtesy of Richard P. Usatine, MD.)

- Symptom control with topical steroids and antihistamines is the main goal.

76 PEMPHIGOID GESTATIONIS

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 37-year-old pregnant woman presented to the hospital with severe preeclampsia. After all medical methods were tried and failed to control her severe preeclampsia, a joint decision was made to induce labor to save the life of the mother. The pregnancy was too early for the fetus to survive. The following day she began to develop the lesions seen in **Figures 76-1** through **76-4**. A diagnosis of pemphigoid gestationis was made. Her past history includes antiphospholipid syndrome with multiple pregnancy losses but two live children. This was her third episode of pemphigoid gestationis. A photograph of her previous episode is included to see how similar the periumbilical bulla was to her current episode of pemphigoid gestationis. A new biopsy was not performed given that her previous biopsy was on file and the clinical picture was consistent with a recurrence of this disease. She was treated with oral prednisone and began to improve rapidly (**Figure 76-5**).

INTRODUCTION

Pemphigoid gestationis is a rare autoimmune bullous dermatosis of pregnancy. The disease was originally known as herpes gestationis because of its visual similarities to herpes simplex infection. However, that term has fallen out of favor because pemphigoid gestationis is not associated with active or prior herpes virus infection.

SYNONYMS

Herpes gestationis.

EPIDEMIOLOGY

- Pemphigoid gestationis is a rare disease that occurs in 1 in 1700 to 1 in 50,000 pregnancies.^{1,2}
- Pemphigoid gestationis has an estimated prevalence of 1 case in 50,000 to 60,000 pregnancies in the United States.
- It has been linked to the presence of human leukocyte antigen (HLA)-DR3, HLA-DR4, or both.³
- It is rarely associated with molar pregnancies and choriocarcinoma.³

ETIOLOGY AND PATHOPHYSIOLOGY

- Pemphigoid gestationis, which has classically been called herpes gestationis, is defined as a bullous or blistering disease that is associated with pregnancy or with trophoblastic tumors.

FIGURE 76-1 Pemphigoid gestationis in the pruritic papular stage. The lesions resemble the target lesions of erythema multiforme. (Courtesy of Richard P. Usatine, MD.)

FIGURE 76-2 Pemphigoid gestationis with bullous lesions on the wrist. (Courtesy of Richard P. Usatine, MD.)

- As there is no connection with a herpes virus, the preferred name is now pemphigoid gestationis. It is associated with an increased risk of fetal morbidity and mortality.
- The pathophysiology of the disease involves immunoglobulin (Ig) G antibodies that attack cells in the skin.
- The IgG attacks the same antigen (bullous pemphigoid antigen) as in bullous pemphigoid.² This antigen is a transmembrane protein that is part of the hemidesmosome, which connects the basal cells of the epidermis to the basement membrane.
- When the inflammatory response is activated, the hemidesmosomes are destroyed and the epidermis separates from the dermis.²
- It is unknown why some patients form these antibodies.
- Rarely, pemphigoid gestationis persists for years postpartum.^{1,2}
- There is no scarring from the lesions.

RISK FACTORS

Pemphigoid gestationis in a prior pregnancy.

DIAGNOSIS

CLINICAL FEATURES: HISTORY AND PHYSICAL

- Pemphigoid gestationis typically erupts during the second or third trimester and, rarely, postpartum and first trimester. Symptoms may abate at the end of pregnancy; however, flares can occur immediately after delivery.
- Pruritus sometimes precedes the rash and vesicles may develop early.
- The initial manifestations are erythematous urticarial patches and plaques, which typically start around the umbilicus. The lesions progress to tense vesicles. (**Figures 76-1 to 76-5**).

TYPICAL DISTRIBUTION

The rash begins on the trunk around the umbilicus as pruritic papules or plaque and may progress to bullae (**Figures 76-4 to 76-5**).^{1,2} Lesions may occasionally be seen on the palms and soles, and rarely on the face or mucous membranes.

LABORATORY TESTING

There are no diagnostic laboratory tests.

BIOPSY

Skin biopsy including the edge of a blistering lesion reveals a subepidermal vesicle with a perivascular lymphocytic and eosinophilic infiltrate.

- Eosinophils may appear at the dermoepidermal junction and inside the vesicle; the degree of eosinophilia correlates with disease severity.
- Basal cell necrosis and papillae edema are usually present.

A skin biopsy of perilesional skin for indirect immunofluorescent staining shows complement 3 in a homogeneous linear band at the basement membrane. This is pathognomonic for pemphigoid gestationis.

FIGURE 76-3 Pemphigoid gestationis. Close-up of a bullous lesion on the abdomen. (Courtesy of Richard P. Usatine, MD.)

FIGURE 76-4 Pemphigoid gestationis with a bulla in the umbilicus. Lesions typically begin in the periumbilical region. (Courtesy of Richard P. Usatine, MD.)

DIFFERENTIAL DIAGNOSIS

- Papular urticarial papules and plaques of pregnancy (PUPPP) may mimic pemphigoid gestationis, especially early in the disease. However, PUPPP usually begin in the striae, whereas pemphigoid gestationis is usually periumbilical. Most importantly, PUPPP does not develop large bullae as does pemphigoid gestationis (see Chapter 75, Pruritic Urticarial Papules and Plaques of Pregnancy).
- Dermatitis herpetiformis is a very pruritic, vesicular skin eruption. It is a chronic recurrent symmetric vesicular eruption that is usually associated with gluten-induced enteropathy. Men are more often affected than women (see Chapter 186, Other Bullous Disease).
- Erythema multiforme secondary to pregnancy, infection, or drug exposure can mimic pemphigoid gestationis. Biopsy with routine histology can usually distinguish between these disorders (see Chapter 177, Erythema Multiforme, Stevens-Johnson Syndrome, and Toxic Epidermal).
- Contact dermatitis and drug reactions may have a similar appearance and history of exposure to a contact allergen or medication can help to distinguish between these reactions and pemphigoid gestationis (see Chapters 146, Contact Dermatitis and 203, Cutaneous Drug Reactions).
- Bullous pemphigoid produces similar lesions, but rarely starts in pregnancy or starts around the umbilicus (see Chapter 184, Bullous Pemphigoid).
- Urticaria may appear similar to early pemphigoid gestationis (see Chapter 150, Urticaria and Angioedema).

MANAGEMENT

NONPHARMACOLOGIC

Tepid baths, compresses, and emollients may help alleviate pruritus.

MEDICATIONS

- Topical steroids and oral antihistamines should be administered in early or mild cases, but are usually ineffective in more severe cases. **SOR C**
- Systemic steroids, such as prednisone (0.5 mg/kg per day), are effective to control most cases.⁴ **SOR C** The dose may be tapered and eventually discontinued in many pregnancies.

PROGNOSIS

Pemphigoid gestationis typically regresses spontaneously without scarring within weeks to months after delivery. It may recur in subsequent pregnancies or may be precipitated by the use of oral contraceptives.

FOLLOW-UP

- Follow-up of the mother and child are essential because of the following issues:

FIGURE 76-5 Close-up of a large bulla in the umbilicus in a previous case of pemphigoid gestationis in the same patient 5 years before. (Courtesy of University of Texas Health Sciences Center, Division of Dermatology.)

- The fetus during a pregnancy in which the mother has pemphigoid gestationis is at risk for growth restriction and prematurity.
- Mild placental insufficiency may result from an immune response between placental antigens and the disease-related antibodies.⁷
- Cutaneous involvement in infants of affected mothers is rare (5% to 10% have urticarial, vesicular, or bullous lesions) and abates with clearance of the maternal antibodies.⁶
- The mother is at high risk of recurrent pemphigoid gestationis with subsequent pregnancies and at an increased lifetime risk of Graves disease.^{2,5}

PATIENT EDUCATION

- Pemphigoid gestationis may abate prior to delivery, but 75% of patients flare postpartum requiring reinstatement of treatment.
- At least 25% of patients will flare with oral contraceptive pill use.
- Most cases spontaneously resolve in the weeks to months following delivery.
- The disease usually recurs with future pregnancies and often worsens with repeated episodes, but may also skip some pregnancies.^{2,5}

77 FIRST TRIMESTER OBSTETRICAL ULTRASOUND

E.J. Mayeaux, Jr., MD

Danielle Cooper, MD

PATIENT STORY

A 22-year-old woman presents with no menstrual period for approximately 2 months (she has irregular menses.) She is complaining of morning sickness but is otherwise feeling well. A urine pregnancy test confirms she is pregnant. **Figure 77-1** shows a fetus of 9 weeks estimated gestational age (EGA).

INTRODUCTION

Obstetrical ultrasound has become a vital tool in our ability to properly care for the pregnant patient. Vast technologic improvements have made visualization of the pregnancy even better and improved our diagnostic capabilities, ranging from the normal pregnancy to the extremely early ectopic pregnancy. Ultrasonography (US) allows for a relatively detailed assessment of fetal gestational age, development, number of fetuses, and anatomy in utero. Most pregnancies in the United States undergo ultrasound imaging for various indications.

EPIDEMIOLOGY

- Women who receive antenatal care have lower maternal and perinatal mortality and better pregnancy outcomes.¹ However, the optimal components of prenatal care have not been rigorously examined in well-designed studies.
- In the United States in 2003, 84.1% of pregnant women obtained prenatal care in the first trimester, and only 3.5% received no care or initiated prenatal care in the third trimester.

ETIOLOGY AND PATHOPHYSIOLOGY

- Ultrasound is used to estimate gestational age and to calculate the expected date of delivery (EDD). Ultrasound is especially helpful when menses are irregular, the last menstrual period (LMP) is unknown, or in patients who conceived while using hormonal contraceptives. A Cochrane review noted with more accurate dating there was a reduction in intervention for postterm pregnancy.²
- The Routine Antenatal Diagnostic Imaging with Ultrasound (RADIUS) trial was a randomized trial of routine obstetrical ultrasound screening.³ It included more than 15,000 women in the United States. The trial showed that routine ultrasound screening was associated with a significantly increased detection of fetal anomalies, but no improvement in any perinatal outcome, including mortality, preterm birth, birth weight, and neonatal morbidity.

FIGURE 77-1 Ultrasound examination of a fetus of 9 weeks estimated gestational age. The ultrasound was performed with a vaginal probe and the membranes are visible. (Courtesy of E.J. Mayeaux, Jr., MD.)

- First trimester vaginal bleeding is found in 20% to 40% of pregnancies. The differential diagnoses include possible spontaneous abortion, ectopic pregnancy, and gestational trophoblastic disease.
- Ectopic pregnancy causes a significant degree of morbidity and mortality if untreated, often through tubal rupture with potentially life-threatening hemorrhage. Identification of an intrauterine pregnancy effectively excludes the possibility of an ectopic in almost all cases, unless conception involved assisted reproductive technology.
- Threatened, inevitable, incomplete, or complete spontaneous abortion may cause first trimester bleeding. Up to one-third of recognized pregnancies end in early pregnancy loss. Ectopic pregnancy may also be a concern. US may be used to determine if a gestational sac or yolk sac is present in the uterus.
- First trimester transvaginal ultrasound used in conjunction with serum screening is the most sensitive noninvasive technique to detect aneuploidy. When performed in the first trimester, nuchal translucency as well as serum pregnancy-associated plasma protein A (PAPP-A) and β -human chorionic gonadotropin (β -hCG) levels are evaluated, which effectively detect 82% to 87% of trisomy 21. Integrated screening would also include a quad screen in second trimester, which carries a 94% to 96% detection rate.⁴

DIAGNOSIS

- The goals of a basic first trimester ultrasound examination include³:
 - Confirm the presence of an intrauterine (or evaluate suspected extrauterine) pregnancy.
 - Assess gestational age.
 - Determine fetal viability.
 - Determine the cause of vaginal bleeding.
 - Evaluate pelvic or lower abdominal pain.
 - Determine whether a multiple gestation is present.
 - Evaluate maternal pelvic organs for congenital or acquired abnormalities.
- Fetal crown-rump length is used to calculate gestational age and may be performed via the transvaginal or the transabdominal route. Because the variation in size from fetus to fetus is minimal in the first trimester and minimal flexion, this is the optimal time to obtain an estimate of gestational age. Transvaginal US is typically used early for evaluation of the gestational sac, yolk sac, and developing embryo, while transabdominal US usually provides better visualization later in the first trimester. In obese patients, transvaginal US in early pregnancy can provide better visualization for more accurate dating.
- During the first 5 weeks of pregnancy, the endometrium has a “trilaminar” appearance, and usually does not show distinct evidence of an intrauterine pregnancy. The gestational sac is the first detectable sign on ultrasound. Initial gestational age measurements are based on diameter of the sac. The yolk sac (**Figure 77-2**) is the first anatomic structure to appear within the gestational sac around the fifth week of gestation. A gestational sac diameter of 8 mm or greater with an empty or no fetal pole yolk sac indicates an abnormal gestation.⁵
- The embryonic disc becomes visible at about a gestational age of 5 to 6 weeks.⁶ If the embryo is visible, but too small to measure, detection of cardiac activity establishes a gestational age of

FIGURE 77-2 Ultrasound examination of a 9-week EGA twin with abdominal probe. The arrow is pointing to the yolk sac. Only one of the twins is visible. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 77-3 Ultrasound examination of a 13-week 3-day fetus by dates showing the head and spine with crown-to-rump length measurement of 6.98 cm. This represents an EGA of 13-weeks 3-days by ultrasound estimation. (essentially equal to dates.) (Courtesy of E.J. Mayeaux, Jr., MD.)

approximately 6 weeks. Direct measurement of the crown-rump length of the embryo provides the most accurate estimate of gestational age once the fetal pole is evident (Figure 77-3). The crown-rump length is the mean of three measurements of the longest straight-line length of the embryo from the outer margin of the cephalic pole to the rump.

- The biparietal diameter may be used later in the first trimester (Figure 77-4). It is highly reproducible and can predict gestational age within 7 days when measured between 14 and 20 weeks of gestation. The biparietal diameter should be measured on a plane of section that intersects both the third ventricle and thalami. The falx cerebri should be visible. The cursors are placed on the outer edge of the proximal skull and the inner edge of the distal skull to take the measurement. The femur length can be assessed by 10 weeks gestational age, but is more accurate after 20 weeks' gestation.

78 SECOND TRIMESTER OBSTETRICAL ULTRASOUND

E.J. Mayeaux, Jr., MD
Danielle B. Cooper, MD

PATIENT STORY

A 23-year-old pregnant gravida 2, para 1 woman is being seen for ultrasound because of her uncertain dates. Her best recollection of her last period gave her an estimated gestational age (EGA) of 19 weeks. Her vital signs are normal and her fundal height is 20 cm. **Figures 78-1 to 78-3** are still images taken from her ultrasound examination demonstrating an EGA of 21 weeks and 6 days by measurement of the baby's biparietal diameter (BPD), head circumference (HC), abdominal circumference (AC), and femur length (FL). All four measurements allow the computer to calculate an estimated fetal weight of 431 g. The pregnancy proceeded without complications and the patient delivered a healthy boy at 40³/₇ weeks based on the ultrasound calculated estimated date of delivery. No interventions were needed for postdates because of the ultrasound calculations earlier in the pregnancy.

INTRODUCTION

The ideal time to perform an obstetric ultrasound is between 18 and 20 weeks' gestation. The fetus has developed all of its organ systems and is large enough to visualize these in detail. If resources are limited or patient costs are an issue, the second trimester ultrasound provides the most bang for the buck.

INDICATIONS FOR ULTRASOUND

- Second and third trimester ultrasound examination can be used to determine fetal number and presentation, and for documentation of fetal cardiac activity, placental location, and amniotic fluid volume.
- Second trimester is a good time to perform ultrasound for fetal assessment for gestational age and weight, and it is also an integral part of performing diagnostic amniocentesis.
- If only a single ultrasound can be performed on a patient, optimal timing is 18 to 20 weeks. Fetal anatomy is best seen during this interval. If fetal abnormalities are detected, a more detailed examination (level 2 ultrasound) by a specialized sonographer is indicated.
- Ultrasound examination is indicated to establish the number of fetuses when a multiple gestation pregnancy is suspected. Risk factors for a multiple gestation pregnancy include assisted reproductive technology, family history of twins (or higher multiples), and uterine size larger than that expected by menstrual dating.

FIGURE 78-1 Transvaginal cervical length of a 24-week uterus. The hyperechoic line identifies the glandular tissue of the cervix and correct positioning to include the entire cervix. Measurement is from the internal os traced out to the external os. The fetal head is visible in this shot but not necessary for the measurement. (Courtesy of Danielle Cooper, MD.)

FIGURE 78-2 Ultrasound examination of a 21-week EGA fetus showing measurement of the baby's biparietal diameter (BPD) and head circumference (HC). Note the presence of the falx cerebri and the thalamus (TH) to ensure the measurement is at the right anatomic level. (Courtesy of E.J. Mayeaux, Jr., MD.)

The number of fetuses can be best established by obtaining an image that includes a cross-section of all fetal poles that have distinct cardiac activity within a single frame.

- The cervix and lower uterine segment may be imaged in the second trimester to look for funneling (membranes protruding into the cervical canal), a short cervix that is a significant risk factor for preterm labor.

The placental location, appearance and relationship to the internal cervical os should be recorded.¹

PATHOPHYSIOLOGY

- Fetal abnormalities that may be reliably diagnosed by ultrasound include achondroplasia, anencephaly, cleft lip, clubfoot, duodenal atresia, fetal hydrops, gastroschisis, hydrocephalus, omphalocele, transposition of the great vessels, cardiac, pulmonary and renal abnormalities, and spina bifida. If anomalies are suspected, a level 2 ultrasound with a perinatologist is indicated.
- Up to 5% of pregnancies will have placentas that partially or completely cover the internal cervical os at 16 to 18 weeks of gestation. Only 1 in 10 of these will continue to cover the internal os in the late third trimester.² Placentas that are clear of the cervix in early pregnancy will not encroach upon it later.

INDICATIONS FOR OB ULTRASOUNDS IN SECOND TRIMESTER

- Evaluating the possibility of a fetal anomaly is best done by ultrasound examination after 16 weeks of gestation as earlier examination may be limited by fetal size and development.
- The sensitivity and specificity of the procedure for detecting congenital abnormalities varies depending upon the specific defect, the gestational age, the quality of the ultrasound unit, and the skill of the ultrasonographer.
- Ultrasound examination is the main diagnostic modality used to evaluate second and third trimester bleeding. The major placental causes of vaginal bleeding at this time are placenta previa and abruptio placentae. A transvaginal obstetric ultrasound examination can identify placental location, and is safe even when placenta previa is present. Preterm labor is another cause of vaginal bleeding and the cervical length can be measured transvaginally to assess this risk. The normal cervical length can be seen in **Figure 78-1**. The images should be obtained after the mother has emptied her bladder to avoid displacement of the anterior lower uterine segment thus producing a false-positive test.³
- Fetal intrauterine growth limiting disorders are more likely when the uterine size is less than appropriate for gestational age, a prior pregnancy has been affected by growth restriction, with maternal hypertension, and in multiple gestations. Ultrasound cannot distinguish between a constitutionally small fetus and a pathologically small fetus. Decreased amniotic fluid volume and below normal interval growth make placental insufficiency more likely.

FIGURE 78-3 Ultrasound examination of a 21-week EGA fetus showing measurement of the baby's abdominal circumference (AC). Note how the stomach (St), spine (SP), and portal vein (PV) are all visible to ensure that the measurement is at the right anatomic level. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 78-4 Ultrasound measurement of the same baby's femur length giving an EGA of 21 weeks and 6 days. Note the buttocks and penis are visible. All four measurements from **Figures 78-1 to 78-3** and this figure allow the computer to calculate an estimated fetal weight (EFW) of 431 grams. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 78-5 Ultrasound examination of a 15-week EGA fetus showing the baby's face. (Courtesy of E.J. Mayeaux, Jr., MD.)

PERFORMING THE PROCEDURE

- The four standard biometric parameters commonly used to estimate gestational age and/or fetal weight in the second trimester are: BPD, HC (**Figure 78-2**), AC (**Figure 78-3**), and FL (**Figure 78-4**).⁴ They are usually obtained by transabdominal ultrasound examination, and the fetal weight is calculated.
- The BPD (**Figure 78-2**) is a highly reproducible measurement and can predict gestational age within ± 7 days when the ultrasound is performed between 14 and 20 weeks' gestation, although the best time to get an accurate date is in the first trimester. The BPD should be measured on a plane that includes both the third ventricle and the thalamus. The cursors are placed on the outer edge of the proximal skull and the inner edge of the distal skull and the BPD measured.
- The cephalic index is ratio of the BPD and the occipitofrontal diameter multiplied by 100. It should be used where the BPD may be inaccurate, such as with breech presentations, oligohydramnios, premature rupture of the membranes, and neural tube abnormalities.
- The measurement of fetal HC also accurately estimates gestational age, and is especially useful in the setting of growth disorders (**Figure 78-2**). The accuracy decreases in the second half of pregnancy. The HC should be measured on a plane that includes the third ventricle, the thalamus, the cavum septum pellucidum anteriorly, and the tentorial hiatus posteriorly. Unlike the BPD measurements, the HC measurement is obtained by placing the cursors on the outer margins of the calvarium bilaterally.
- The AC (**Figure 78-3**) is the least accurate in predicting gestational age, being accurate within 2 weeks in the second trimester. It is most often used for estimations of fetal weight and interval growth evaluations rather than fetal dating. The measurement should be taken at the level of the largest diameter of the fetal liver where the right and left portal veins join. The four calipers are placed around the abdomen on the skin edge to draw a circular line for AC measurement.
- FL (**Figure 78-4**) can be measured and is accurate to within 1 week before 20 weeks' gestation. Align the transducer along the long axis of the femoral bone and visualize either the femoral head or the greater trochanter proximally, and the end of the femur or the femoral condyle distally. Make sure you are measuring the femur and not another long bone in the arm or leg. Place the calipers at the bone and cartilage junction and measure only ossified bone, not including the femoral head.
- Many providers will often show expectant parents images of the baby's face (**Figures 78-5 and 78-6**), hands (**Figure 78-7**), and sex (**Figures 78-8 and 78-9**).
- The placenta and its relationship to the cervix should be examined for signs of placenta previa.

Cervical length or funneling of the cervix should be measured if there is a history of or current evidence of preterm labor or history of incompetent cervix. Cervical length is determined as the distance between the internal and external os. In patients at risk for cervical shortening or incompetence the operator can apply fundal pressure or scan the patient in the standing position to help identify these women³ (**Figure 78-10**).

79 THIRD TRIMESTER OBSTETRIC ULTRASOUND

E.J. Mayeaux, Jr., MD
Danielle B. Cooper, MD

PATIENT STORY

A 26-year-old woman gravida 3, para 2-0-0-2 with a singleton pregnancy at 27 weeks' gestation is concerned because her sister had a fetal demise and she thinks her baby is moving less. An ultrasound demonstrating normal anatomy (**Figures 79-1 to 79-3**) and strong fetal heart motion is very reassuring (**Figure 79-4**).

INTRODUCTION

Ultrasound usage in the third trimester of pregnancy is most often utilized to determine fetal number, presentation, and growth issues. This later pregnancy scan is also used to document fetal cardiac activity, placental location, and amniotic fluid volume, as well as provide a method for antenatal fetal assessment.

INDICATIONS FOR USE

- A Cochrane review of 7 studies showed no difference in obstetric, antenatal, or neonatal interventions between women undergoing routine late ultrasound examination after 24 weeks and those who did not.¹ In addition, there was no difference in perinatal outcome measures, such as admission to a neonatal intensive care unit, birth-weight less than 10th percentile, or perinatal mortality.
- Hydrops fetalis is the accumulation of fluid in fetal tissues and body cavities, usually a result of immune pathologic conditions (**Figure 79-5**). Serial ultrasound examinations are useful for following pregnancies at risk for developing hydrops or to evaluate treatment. As well as utilizing middle cerebral artery peak-systolic velocity as a noninvasive tool to predict fetal anemia.²
- Ultrasound may also be used to evaluate third trimester bleeding. The major placental causes of vaginal bleeding at this time are placenta previa (**Figure 79-6**) and abruptio placentae.
- Ultrasound can safely image maternal abdominal organs during pregnancy. Ovarian cysts, uterine leiomyoma, renal obstruction, and gallbladder or liver disease can be evaluated without using ionizing radiation.

In pregnancies complicated by fetal growth restriction and maternal hypertensive disorders, umbilical artery Doppler sonography can be used for fetal surveillance and monitoring well-being. The values measured are peak-systolic frequency shift (S) and end-diastolic frequency shift (D). This S-to-D ratio gives information about downstream impedance to flow. For example uteroplacental insufficiency will show rising impedance to fetal placental vascular bed, which shows a decline in end-diastolic velocity and an overall increase in these Doppler indices.³

FIGURE 79-1 Ultrasound examination of a 27-week estimated gestational age (EGA) fetus showing measurement of the baby's humerus. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 79-2 Ultrasound examination of a 27-week EGA fetus showing the baby's stomach (St), abdomen, spine (SP), and left portal vein (PV). (Courtesy of E.J. Mayeaux, Jr., MD.)

If there is an increased risk for in utero fetal demise or significant risk factors for fetal anemia then fetal surveillance can be performed with the biophysical profile (BPP). This is the sonographic assessment of four fetal variables: fetal movement, fetal tone, fetal breathing, and the amniotic fluid volume, plus the results of the nonstress testing.³

VALUE OF ULTRASOUND IN THIRD TRIMESTER

- Ultrasound-based determination of estimated date of delivery (EDD) has been shown to improve dating and thus reduce intervention for postterm pregnancy. One randomized controlled trial evaluated the effect of routine ultrasound examinations at 18 and 32 weeks of gestation on the accuracy of dating and pregnancy outcome in a low-risk population.⁴ They found that ultrasound screening reduced the incidence of induced labor for postterm pregnancy by 70%, and also reduced the incidence of induction for all causes. They also found that the proportion of 5-minute Apgar scores less than 8 and the need for positive pressure ventilation were both lower in the screened group.
- Although ultrasound EDD determination as late as 34 weeks can reduce the number of pregnancies diagnosed as postterm, first trimester ultrasound in a low-risk population is more effective than later ultrasound in decreasing postterm pregnancy.
- Accurate assessment of gestational age is important so as not to inappropriately initiate tocolysis for near-term labor.
- Signs suggestive of fetal maturity may also be found on ultrasound. The femoral epiphyseal ossification center can be visualized by 32 weeks' gestational age, and proximal tibial center can be visualized by 35 weeks' gestational age. The proximal humeral epiphysis also appears in the late third trimester and correlates well with fetal lung maturity.
- Twin pregnancies are at increased risk of complications, such as fetal heart rate abnormalities and complications as a result of malpresentation. When both twins are found on ultrasound to be vertex (42% of twins) a trial of labor with the goal of a vaginal delivery is appropriate. When one twin is nonvertex (38% of twins) options include cesarean delivery of both twins, or attempted vaginal delivery of one or both twins.^{5,6}
- Parents are now paying for 4D ultrasounds (3D images in real time, time being the fourth dimension) so that they can see and get pictures of their developing child. Although the 4D ultrasound is not a standard medical device (**Figure 79-7**), it is being utilized to better characterize certain anomalies, such as facial clefts, neural tube defects, and skeletal malformations.⁷

If there is suspicion of unusual fetal growth, restricted or macrosomic, a third trimester growth scan is obtained for evaluation and continued plan of care.

The BPP is a noninvasive, easily performed, accurate means for predicting the presence of significant fetal anemia. Approximately 70% to 90% of late fetal deaths display evidence of fetal compromise prior to demise.³ Ultrasound detection of these fetal signs can allow appropriate intervention to ideally prevent adverse fetal sequelae.

Umbilical artery and middle cerebral artery Doppler measurements should be integrated with other existing modalities of antepartum fetal monitoring to determine their clinical usefulness.³

FIGURE 79-3 Ultrasound examination of a 27-week EGA fetus showing measurement of the baby's biparietal diameter (BPD). (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 79-4 Ultrasound examination of a 27-week EGA fetus showing all four chambers of the baby's heart. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 79-5 Ultrasound examination showing scalp edema (E) associated with hydrops fetalis. (Courtesy of E.J. Mayeaux, Jr., MD.)

FOLLOW-UP

- Once BPPs are initiated in women requiring fetal surveillance, this test should be repeated on a weekly or twice weekly basis until delivery.

When a patient has placenta previa diagnosed on ultrasound, advise patient to avoid coitus, digital cervical examination, and exercise. Counsel her to seek immediate medical attention if there is any vaginal bleeding or uterine contractions. Advise her that cesarean delivery is the delivery route of choice.⁸

SECTION 2 VAGINITIS AND CERVICITIS

80 OVERVIEW OF VAGINITIS

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 39-year-old woman presented to her physician with a malodorous vaginal discharge. On exam, a thin white discharge was seen covering the introitus (**Figure 80-1**). A speculum exam revealed a thin whitish gray discharge and a distinct fishy odor. The pH of the discharge was 4.6, and 40% of the epithelial cells on her wet prep were clue cells (**Figure 80-2**). She was diagnosed with bacterial vaginosis and treated with oral metronidazole.

INTRODUCTION

Vaginal discharge is a frequent presenting complaint in primary care. The three most common causes are bacterial vaginosis, candidiasis, and trichomoniasis. However, a significant number of patients with vaginal discharge will have some other condition, such as atrophic vaginitis. Providers must refrain from “diagnosing” a vaginitis based solely on the color and consistency of the discharge, as this may lead to misdiagnosis and may miss concomitant infections.¹

EPIDEMIOLOGY

The reported rates of chlamydia and gonorrhea are highest among females ages 15 to 19 years. Adolescents are at greater risk for sexually transmitted diseases (STDs) because they frequently have unprotected intercourse, are biologically more susceptible to infection, are often engaged in partnerships of limited duration, and face multiple obstacles to utilization of health care.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- The quantity and quality of normal vaginal discharge in healthy women vary. Physiologic leukorrhea refers to generally nonmalodorous, mucousy, white or yellowish vaginal discharge in the absence of a pathologic cause. It is not accompanied by signs and symptoms, such as pain, pruritus, burning, erythema, or tissue friability. However, slight malodor and irritative symptoms can be normal for some women at certain times.² Physiologic leukorrhea is usually a result of estrogen-induced changes in cervicovaginal secretions.
- Noninfectious causes of vaginitis include irritants (e.g., scented panty liners, spermicides, povidone-iodine, soaps and perfumes, and some topical drugs) and allergens (e.g., latex condoms, topical

FIGURE 80-1 Thin white discharge from bacterial vaginosis seen covering the introitus prior to speculum exam. (Courtesy of Seattle STD/HIV Prevention Training Center, University of Washington.)

antifungal agents, chemical preservatives) that produce hypersensitivity reactions.

- Before starting an examination, determine whether the patient douches recently, because this can lower the yield of diagnostic tests and increase the risk of pelvic inflammatory disease.³ Patients who have been told not to douche will sometimes start wiping the vagina with soapy washcloths, which also irritates the vagina and cervix and may cause a discharge. Douching is associated with increases in bacterial vaginosis and acquisition of sexually transmitted infections when exposed. However, recent studies indicate that douching with plain water once a week or less did not disturb normal flora.^{4,5}
- There are many causes of vaginitis in humans. Infectious causes include bacterial vaginosis (40% to 50% of cases) (see **Figures 80-1 and 80-2**), vulvovaginal candidiasis (20% to 25%), and trichomonas (15% to 20%) (**Figure 80-3**).⁶ Less common causes include atrophic vaginitis, foreign body (especially in children), cytolytic or desquamative inflammatory vaginitis, streptococcal vaginitis, ulcerative vaginitis, and idiopathic vulvovaginal ulceration associated with HIV infection.
- Rarer noninfectious causes include chemicals, allergies, hypersensitivity, contact dermatitis, trauma, postpuerperal atrophic vaginitis, erosive lichen planus, collagen vascular disease, Behçet syndrome, and pemphigus syndromes.

DIAGNOSIS

CLINICAL FEATURES

- Examine the external genitalia for irritation or discharge (see **Figure 80-2**). Speculum examination is done to determine the amount and character of the discharge (**Figure 80-4**). A chlamydia and gonorrhea test should always be done in sexually active females with a vaginal discharge. Look closely at the cervix for discharge and signs of infection, dysplasia, or cancer (**Figure 80-3**). Bimanual examination may show evidence of cervical, uterine, or adnexal tenderness. **Table 80-1** shows diagnostic values for examination of vaginitis.
- Vaginal pH testing can be helpful in the diagnosis of vaginitis. The pH can be checked by applying pH paper to the vaginal sidewall. Do not place the pH paper in contact with the cervical mucus. A pH above 4.5 is seen with menopausal patients, trichomonas infection, or bacterial vaginosis.
- Wet preps are obtained by applying a cotton-tipped applicator to the vaginal sidewall and placing the sample into normal saline. A drop of the suspension is then placed on a slide and examined for the presence and number of white blood cells (WBCs), trichomonads, candidal hyphae, or clue cells (**Figure 80-1**).
- A KOH prep is made by adding a drop of KOH solution to a drop of saline suspension of the discharge. The KOH lyses epithelial cells in 5 to 15 minutes (faster if the slide is warmed briefly) and allows easier visualization of candidal hyphae. The use of KOH with DMSO allows for quicker lyses of the epithelial cells and immediate examination of the smear.
- Another diagnostic procedure is the “whiff” test, which is performed by placing a drop of KOH on a slide of the wet prep and

FIGURE 80-2 A wet mount of vaginal discharge in saline under high-power light microscopy. Note the presence of vaginal epithelial cells, smaller white blood cells (polymorphonucleocytes), and bacteria. The bacteria are the coccobacilli of *Gardnerella vaginalis* covering the cell membranes of the two vaginal epithelial cells near the lower end of the field. These are clue cells seen in patients with bacterial vaginosis. (Courtesy of Richard P. Usatine, MD.)

FIGURE 80-3 Colposcopic view of the cervix in a patient infected with trichomonas vaginalis. Note the frothy discharge with visible bubbles and the cervical erythema. (Courtesy of Seattle STD/HIV Prevention Training Center, University of Washington.)

TABLE 80-1 Diagnostic Values for Vaginal Infections

Diagnostic Criteria	Normal	Bacterial Vaginosis	Trichomonas Vaginitis	Candida Vulvovaginitis
Vaginal pH	3.8 to 4.2	>4.5	4.5	<4.5 (usually)
Discharge	White, thin, flocculent	Thin, white, gray	Yellow, green, or gray, frothy	White, curdy, "cottage cheese"
Amine odor "whiff" test	Absent	Fishy	Fishy	Absent
Microscopic	Lactobacilli, epithelial cells	Clue cells, adherent cocci, no white blood cells	Trichomonads, white blood cells >10/hpf	Budding yeast, hyphae, Pseudohyphae

(Courtesy of E.J. Mayeaux, Jr., MD.)

smelling for a foul, fishy odor. The odor is indicative of anaerobic overgrowth or infection. The "whiff" test is positive if the fishy amine odor is detected during the exam and it is then not necessary to add KOH and "whiff" again.

LABORATORY TESTING (INCLUDE ANCILLARY TESTING TOO)

- Nucleic acid amplification tests are highly sensitive tests for *Neisseria gonorrhoeae*, *Chlamydia*, and *Chlamydia trachomatis* that can be performed on genital specimens or urine. Urine screening for gonorrhea, chlamydia, or both using nucleic acid amplification test can be used successfully in difficult-to-reach adolescents.⁷

MANAGEMENT

- Management is based on the identification of the causative agent.
- Treatment for physiologic leukorrhea is unnecessary.
- Management of vaginal irritants and allergens involves identifying and eliminating the offending agents. However, irritants and allergens can often be difficult to identify.
- Health food store lactobacilli are the wrong strain and do not adhere well to the vaginal epithelium. Ingestion of live-culture, nonpasteurized yogurt does not significantly change the incidence of candidal vulvovaginitis or bacterial vaginosis.⁸

81 ATROPHIC VAGINITIS

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 60-year-old woman with vaginal dryness and irritation is seen to follow-up on an inflammatory Pap smear. She denies discharge, odor, douching, and sexually transmitted disease (STD) exposure. She does admit to some postcoital bleeding. Her cervix has atrophic changes and an endocervical polyp (**Figure 81-1**). The polyp was removed easily with a ring forceps and no dysplasia was found on pathology.

INTRODUCTION

Vaginal atrophy caused by estrogen deficiency is common and usually is asymptomatic except for vaginal dryness.

SYNONYMS

Vaginal atrophy, vulvovaginal atrophy, urogenital atrophy, senile vaginitis.

EPIDEMIOLOGY

- The average age of menopause is 51 years in the United States.
- Approximately 5% of women experience menopause after age 55 years (late menopause), and another 5% experience the transition between the ages of 40 and 45 years (early menopause). This means that in the United States, most women will live a significant portion of their lives during menopause. Women who in menopause have surgical menopause or have ovarian suppression without estrogen supplementation (progestin-only contraceptives) are susceptible to atrophic changes in their lower genital tract.
- Vaginal dryness occurs in approximately 3% of women of reproductive age, 4% to 21% of women in the menopausal transition, and 47% of women 3 years postmenopause.¹ Internationally, 39% of women experience menopause-related vaginal discomfort.²

ETIOLOGY AND PATHOPHYSIOLOGY

- After menopause, circulating estrogen levels dramatically decrease to a level at least one-sixth their premenopausal levels.³ Changes that occur in the vaginal and cervical epithelium include proliferation of connective tissue, loss of elastin, thinning of the epithelium (**Figure 81-2**), and hyalinization of collagen.
- A long-term decrease in estrogen is generally necessary before symptoms become apparent. Genital symptoms include decreased vaginal lubrication, dryness, burning, dyspareunia, leukorrhea, itching, and yellow malodorous discharge.

FIGURE 81-1 Colposcopic photograph (scanning objective with 10x eyepiece) demonstrating atrophic vaginitis. Note thinned white epithelium, friable epithelium with bleeding, and a cervical polyp. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 81-2 Colposcopic photograph (scanning objective with 10x eyepiece) demonstrating atrophic cervicovaginitis. Note thin white epithelium, relative dryness, and a barely visible cervical os. (Courtesy of E.J. Mayeaux, Jr., MD.)

- Urinary symptoms, such as frequency, hematuria, urinary tract infection, dysuria, and stress incontinence, are usually late symptoms. Over time, the lack of vaginal lubrication often results in sexual dysfunction.
- Cervical polyps (**Figure 81-1**) are pedunculated tumors that usually arise from the endocervical canal mucosa, and are common in patients with atrophic vaginitis. Many will show squamous metaplasia, and they may develop squamous dysplasia. Polyps are most commonly asymptomatic unless they bleed.
- Menopause is the most common cause of atrophic vaginitis. In premenopausal women, radiation therapy, chemotherapy, immunologic disorders, and oophorectomy may greatly decrease production of ovarian estrogen and lead to atrophic vaginitis. Antiestrogen medications may also result in atrophic vaginitis. Women who are naturally premenopausally estrogen deficient, smoke cigarettes, or have not given vaginal birth tend to have more severe symptoms.³

RISK FACTORS

- Age.
- Family history of early menopause.
- Bilateral oophorectomy.
- Spontaneous premature ovarian failure.
- Antiestrogenic medications effects, such as tamoxifen, danazol, medroxyprogesterone acetate.
- Gonadotropin-releasing hormone agonists (leuprolide, nafarelin, goserelin), or antagonists (ganirelix).
- Prolactin elevation as a result of hypothalamic-pituitary disorders with secondary reduction of estrogen secretion.
- Certain chemotherapeutic agents.
- Pelvic radiation therapy.
- Severe systemic lupus erythematosus or rheumatoid arthritis (because of hypothalamic hypogonadism or primary ovarian insufficiency) combined with glucocorticoid therapy cause combined suppression of ovarian and adrenal activity.

DIAGNOSIS

CLINICAL FEATURES

- Diagnosis is clinical, based upon characteristic symptoms and findings. Many women with symptoms of vaginal atrophy do not discuss their condition with a health care provider because they believe their symptoms are a normal part of the aging process.⁴
- Atrophic vaginal and cervical epithelium appears pale, smooth, relatively dry, and shiny (**Figure 81-2**). Inflammation with patchy erythema, petechiae, and friability is common in more advanced cases. The external genitalia may demonstrate diminished elasticity, turgor of skin, sparsity of pubic hair, dryness of labia, erythema (**Figure 81-3**), and fusion of the labia minora.⁵

LABORATORY TESTING

- Laboratory tests to confirm hypoestrogenic findings are typically not necessary.

FIGURE 81-3 The vulva of a postmenopausal woman demonstrating thinning of the hair and thinning and erythema of vulvar skin associated with atrophic vulvitis. (Courtesy of Gordon Davis, MD, Arizona Vulva Clinic, Inc.)

- Serum estradiol levels of less than 20 pg/mL support a clinical diagnosis of a low-estrogenic state. However, values are very laboratory dependent and most assays are neither sufficiently sensitive nor reliable for diagnosis of hypoestrogenic states without clinical signs and symptoms.
- A serum follicle-stimulating hormone (FSH) level greater than 40 mIU/mL is diagnostic of menopause.
- A Papanicolaou smear can confirm the presence of urogenital atrophy. Cytologic examination of smears from the upper one-third of the vagina shows an increased proportion of parabasal cells and a decreased percentage of superficial cells.
- An elevated vaginal pH level (>5), monitored by a pH strip in the vaginal vault, may also be a sign of vaginal atrophy.³

IMAGING

- Testing for associated osteoporosis should be considered if not previously performed.

DIFFERENTIAL DIAGNOSIS

- Atrophic vaginitis symptoms can be mimicked or exacerbated by coinfection of candidiasis, trichomoniasis, or bacterial vaginosis. These can be identified by wet prep, pH, and whiff test (see Chapter 82, Bacterial Vaginosis).
- Sexually transmitted diseases, including gonorrhea, trichomonas, and chlamydia, also may coexist with or mimic atrophic vaginitis. Cultures or nucleic acid amplification tests can identify these infections. It is important not to assume a diagnosis of solely atrophic vaginitis in the postmenopausal patient who presents with urogenital complaints. (Chapter 80, Overview of Vaginitis).
- Contact dermatitis because of environmental agents (e.g., perfumes, deodorants, soaps, panty liners, perineal pads, spermicides, lubricants, or tight fitting/synthetic clothing) may cause erythema, itching, burning, or pain. (Chapter 146, Contact Dermatitis).
- Vulvovaginal lichen planus, which may produce labial fusion. (Chapter 154, Lichen Planus).
- Lichen sclerosus et atrophicus (LSEA) does produce atrophy of the vulva and can be mistaken for the atrophy of estrogen deficiency. It can be recognized by the hour-glass configuration of the atrophy around the vulva and perianal region (**Figure 81-4**). LSEA is treated with a high-potency steroid ointment rather than estrogen.

FIGURE 81-4 Lichen sclerosus et atrophicus with atrophy of the vulva in this 53-year-old woman. Lichen sclerosus et atrophicus can be recognized by the hour-glass configuration of the atrophy around the vulva and perianal region. (Courtesy of Richard P. Usatine, MD.)

MANAGEMENT

NONPHARMACOLOGIC

- Nonhormonal local vaginal moisturizers and lubricants may be used to help maintain natural secretions and comfort during intercourse. Sexual activity has been shown to encourage vaginal elasticity and pliability, and the lubricative response to sexual stimulation. One open-label study indicated that Replens, a bioadhesive vaginal moisturizer, was a safe and effective alternative to estrogen vaginal cream, with both therapies exhibiting statistically significant increases in vaginal moisture, vaginal fluid volume, and vaginal elasticity.⁶ **SOR A**

- Water-based vaginal lubricants include:
 - Slippery Stuff (polyoxyethylene, methylparaben, propylene glycol, isopropanol).
 - Astroglide (glycerin, methylparaben, propylparaben, polypropylene glycol, polyquaternium, hydroxyethylcellulose).
 - K-Y Jelly (glycerin, hydroxyethylcellulose, parabens, and chlorhexidine).
 - Pre-Seed (hydroxyethylcellulose, arabinogalactan, paraben, and Pluronic copolymers), which is promoted for women who are trying to conceive.
- Silicone-based:
 - ID Millennium (cyclomethicone, dimethicone, and dimethiconol).
 - Pjur Eros (cyclopentasiloxane, dimethicone, and dimethiconol).
 - Pink (dimethicone, vitamin E, aloe vera, dimethiconol, and cyclomethicone).
- Oil-based:
 - Elégance Women's Lubricant.
 - Natural oils (such as olive oil).
- Water-based and silicone-based vaginal lubricants are compatible with condom use. Oil-based lubricants may damage latex-based condoms.
- Patients should stop smoking, as women who smoke cigarettes are relatively estrogen-deficient.⁷ **SOR A**

MEDICATIONS

- Estrogen replacement therapy relieves menopausal symptoms including atrophic vaginitis.⁸ **SOR A** Routes of administration include oral, transdermal, and intravaginal. Risks associated with estrogen use include breast cancer, coronary heart disease, stroke, and venous thromboembolism.
- A Cochrane review found that estrogen creams, pessaries, vaginal tablets, and the estradiol vaginal ring appeared to be equally effective for the symptoms of vaginal atrophy.⁸ **SOR A** One trial found significant side effects following conjugated equine estrogen cream administration when compared to tablets causing uterine bleeding, breast pain, and perineal pain. Another trial found significant endometrial overstimulation following use of the conjugated equine estrogen cream when compared to the estrogen vaginal ring. Women appeared to favor the estradiol-releasing vaginal ring for ease of use, comfort of product, and overall satisfaction.⁸ **SOR A**
- The amount of estrogen and the duration of time required to eliminate symptoms depend on the degree of vaginal atrophy, and varies among patients. Progestin therapy should be considered in any woman with an intact uterus to avoid causing endometrial cancer. When oral estrogen is used at typical doses, atrophic symptoms will persist in 10% to 25% of patients.⁹
- Topical administration of estrogen is an excellent treatment for genitourinary symptoms of atrophy, because exposure of other organs can be minimized if low doses of topical estrogens are used. Absorption rates with topical therapy increase with treatment duration because of the enhanced vascularity of the epithelium.
- Vaginal estrogen therapy available in the United States are conjugated estrogens cream (0.625 mg conjugated estrogens/g, 0.5 g of cream intravaginally twice weekly) and estradiol cream (100 mcg estradiol/g of cream, 2 to 4 g of cream intravaginally administered

daily for 2 weeks, then decreased to 1 g of cream 1 to 3 times per week), tablet (10 mcg estradiol/tablet intravaginally daily for 2 weeks then twice weekly), and ring (0.5 mcg estradiol/day, released over 90 days). In Europe and some other countries, estriol cream is also available.

- Vaginal estrogen therapy results in some estrogen absorption into the circulation, although to a lesser degree than oral or transdermal estrogen treatment. In one study, systemic absorption was 30% lower in a study of vaginal versus conjugated estrogen therapy.¹⁰ **SOR B**
- Progestin therapy is probably not necessary to protect against endometrial hyperplasia in women treated with the low-dose ring or intravaginal tablet when used as approved. The systemic estrogen absorption with use of the vaginal creams is difficult to quantify, so some experts recommend use of an opposing progestin for women treated with vaginal estrogen cream.¹¹ **SOR C**

FOLLOW-UP

- Follow-up is needed for all patients placed on estrogen therapy to monitor for estrogen-related side effects. Otherwise, follow-up can be as needed.

PATIENT EDUCATION

- Discuss the risks and benefits of estrogen replacement therapy with patients interested in the use of estrogens. Vaginal lubricants (non-prescription) may safely help prevent pain during intercourse.

82 BACTERIAL VAGINOSIS

E.J. Mayeaux, Jr., MD
Richard P. Usatine, MD

PATIENT STORY

A 31-year-old woman presents with a malodorous vaginal discharge for 3 weeks. There is no associated vaginal itching or pain. She is married and monogamous. She admits to douching about once per month to prevent odor but it is not working this time. On examination, her discharge is visible (**Figure 82-1**). It is thin and off-white. Wet prep examination shows that more than 50% of the epithelial cells are clue cells (**Figure 82-2**). The patient is treated with oral metronidazole 500 mg bid for 7 days with good results.

INTRODUCTION

Bacterial vaginosis (BV) is a clinical syndrome resulting from alteration of the vaginal ecosystem. It is called a vaginosis, not a vaginitis, because the tissues themselves are not actually infected, but only have superficial involvement. Women with BV are at increased risk for the acquisition of HIV, *Neisseria gonorrhoeae*, *Chlamydia trachomatis*, and herpes simplex virus (HSV)-2, and they have increased risk of complications after gynecologic surgery.¹

BV is associated with adverse pregnancy outcomes, including premature rupture of membranes, preterm labor, preterm birth, intraamniotic infection, and postpartum endometritis. However, the only established benefit of BV therapy in pregnant women is the reduction of symptoms and signs of vaginal infection.¹

SYNONYMS

- Vaginal bacteriosis.
- *Corynebacterium vaginosis/vaginalis/vaginitis*.
- *Gardnerella vaginalis/vaginosis*.
- *Haemophilus vaginalis/vaginitis*.
- Nonspecific vaginitis.
- Anaerobic vaginosis.

EPIDEMIOLOGY

- BV is estimated to be the most prevalent cause of vaginal discharge or malodor in women presenting for care in the United States. However, more than 50% of women with BV are asymptomatic.¹ It accounts for more than 10 million outpatient visits per year.² The worldwide prevalence is unknown.

FIGURE 82-1 A 31-year-old woman with homogeneous, thin white malodorous vaginal discharge. (Courtesy of Richard P. Usatine, MD.)

ETIOLOGY AND PATHOPHYSIOLOGY

- Hydrogen peroxide-producing *Lactobacillus* is the most common organism composing normal vaginal flora.¹ In BV, normal vaginal lactobacilli are replaced by high concentrations of anaerobic bacteria such as *Mobiluncus*, *Prevotella*, *Gardnerella*, *Bacteroides*, and *Mycoplasma* species.^{1,2}
- The hydrogen peroxide produced by the *Lactobacillus* may help in inhibiting the growth of atypical flora.
- The odor of BV is caused by the aromatic amines produced by the altered bacterial flora in the vagina. These aromatic amines include putrescine and cadaverine—aptly named to describe their foul odor.

RISK FACTORS

- Multiple male or female partners.^{1,3}
- A new sex partner.¹
- Douching.⁴
- Lack of condom use.¹
- Lack of vaginal lactobacilli.¹
- Prior BV infection.¹

DIAGNOSIS

CLINICAL FEATURES

- Symptomatic patients present with an unpleasant, “fishy smelling” discharge that is more noticeable after coitus (the basic pH of seminal fluid is like doing the whiff test with KOH). There may be pruritus but not as often as seen with *Candida* vaginitis. The physical examination should include inspection of the external genitalia for irritation or discharge. Speculum examination is done to determine the amount and character of the discharge. A nucleic acid amplification test for *N. gonorrhoeae*, *Chlamydia*, and/or *C. trachomatis* (or similar test) should be performed on genital specimens (urethral or cervical) or urine.
- BV is usually clinically diagnosed by finding three of the following four signs and symptoms:
 - Homogeneous, thin, white discharge that smoothly coats the vaginal walls (**Figure 82-3** and **82-4**).
 - Presence of clue cells on microscopic examination (**Figure 82-2**).
 - pH of vaginal fluid >4.5.
 - A fishy odor of vaginal discharge before or after addition of 10% KOH (i.e., the whiff test).¹

LABORATORY TESTING

- Vaginal pH testing can be very helpful in the diagnosis of vaginitis. The normal vaginal pH is usually 3.5 to 4.5. A pH above 4.5 is seen with menopausal patients, *Trichomonas* infection, or BV. A small piece of pH paper is touched to the vaginal discharge during the exam or on the speculum. Do not test a wet-prep sample if saline has been added because the saline alters the pH.

FIGURE 82-2 Clue cell and bacteria seen in bacterial vaginosis. The lower cell is a clue cell covered in bacteria while the upper cell is a normal epithelial cell. Light microscope under high power. (Courtesy of E.J. Mayeaux, Jr, MD.)

FIGURE 82-3 A homogeneous, off-white creamy malodorous discharge that adheres to the vaginal walls and pools in the vaginal vault in a woman with bacterial vaginosis. (Courtesy of Richard P. Usatine, MD.)

- Wet preps are obtained using a cotton-tipped applicator applied to the vaginal sidewall, placing the sample of discharge into normal saline (not water). Observe for clue cells, number of white blood cells, trichomonads, and candidal hyphae. Clue cells are squamous epithelial cells whose borders are obscured by attached bacteria. More than 20% to 25% of epithelial cells seen in BV should be clue cells (**Figure 82-2**).
- A proline aminopeptidase test card (Pip Activity Test Card), a DNA probe-based test for high concentrations of *G. vaginalis* (Affirm VP III), and the OSOM BVBLUE test have shown acceptable performance characteristics compared with Gram stain (gold standard).¹ However, they are more costly than traditional testing without clear advantages.
- Although a test card is available for the detection of elevated pH and trimethylamine, it has low sensitivity and specificity and is not recommended by the Centers for Disease Control and Prevention (CDC).¹
- Culture of *G. vaginalis* is not recommended as a diagnostic tool because it is not specific.
- Pap tests are not useful for the diagnosis of BV because of their low sensitivity.¹

DIFFERENTIAL DIAGNOSIS

- *Trichomonas* also may have the odor of aromatic amines and, therefore, easily confused with BV at first glance. Look for the strawberry cervix on examination and moving trichomonads on the wet prep (Chapter 84, *Trichomonas Vaginitis*).
- *Candida* vaginitis tends to present with a cottage-cheese-like discharge and vaginal itching (Chapter 83, *Candida Vulvovaginitis*).
- Gonorrhea and chlamydia should not be missed in patients with vaginal discharge. Consider testing for these sexually transmitted diseases (STDs) based on patients' risk factors and the presence of purulence clinically and white blood cells on the wet prep (Chapter 85, *Chlamydia Cervicitis*).

MANAGEMENT

- Treatment is recommended for women with symptoms.
- Treatment of male sex partners has not been beneficial in preventing the recurrence of BV.¹ **SOR A**

MEDICATIONS

- The established benefits of therapy for BV in nonpregnant women are to (a) relieve vaginal symptoms and signs of infection and (b) reduce the risk for infectious complications after abortion or hysterectomy.¹ **SOR A** Other potential benefits might include a reduction in risk for other sexually transmitted infections (STIs).¹ **SOR B** **Table 82-1** shows CDC recommended treatments.
- Metronidazole 2 g single-dose therapy has the lowest efficacy for BV and is no longer a recommended or alternative regimen. Clindamycin cream is oil-based and might weaken latex condoms and diaphragms for 5 days after use. Topical clindamycin

FIGURE 82-4 Close up view of the cervix showing the white homogeneous discharge. Note the lack of clumping or “cottage-cheese” appearance usually found with *Candida* infections. (Courtesy of E.J. Mayeaux, Jr., MD.)

TABLE 82-1 CDC Recommended Regimens **SOR A****Metronidazole** 500 mg orally twice a day for 7 days

Clindamycin 300 mg orally twice a day for 7 daysData from Centers for Disease Control and Prevention.¹

preparations should not be used in the second half of pregnancy.¹ Multiple studies and metaanalyses have not demonstrated an association between metronidazole use during pregnancy and teratogenic or mutagenic effects in newborns.¹ **SOR A**

- The only established benefit of therapy for BV in pregnant women is to relieve vaginal symptoms and signs of infection.¹ **SOR A** Additional potential benefits of therapy include (a) reducing the risk for infectious complications associated with BV during pregnancy and (b) reducing the risk for other infections (e.g., other STDs or HIV). Multiple studies and metaanalyses have not demonstrated an association between metronidazole use during pregnancy and teratogenic or mutagenic effects in newborns.⁵
- One randomized trial for persistent BV indicated that metronidazole gel 0.75% twice per week for 6 months after completion of a recommended regimen was effective in maintaining a clinical cure for 6 months.⁶ **SOR B**

- Limited data suggest that oral nitroimidazole followed by intravaginal boric acid and suppressive metronidazole gel for those women in remission might be an option in women with recurrent BV. **SOR B**⁷
- Intravaginal clindamycin cream has been associated with adverse outcomes if used in the latter half of pregnancy.¹

COMPLEMENTARY AND ALTERNATIVE THERAPY

- Extended ingestion of live culture, nonpasteurized yogurt may theoretically increase colonization by lactobacilli and decrease the episodes of BV.⁸ **SOR C** However, health food store lactobacilli are the wrong strain and are not well-retained by the vagina.
- The efficacy of exogenous lactobacillus recolonization with probiotic lactobacilli vaginal gelatin capsules has been reported in two small trials.^{9,10}

PREVENTION

- Avoidance of risk factors is recommended, although asymptomatic BV is common.
- The evidence is insufficient to assess the impact of screening for BV in pregnant women at high risk for preterm delivery.¹

FOLLOW-UP

- Follow-up visits are unnecessary in nonpregnant women if symptoms resolve.¹
- Treatment of BV in asymptomatic pregnant women who are at high risk for preterm delivery might prevent adverse pregnancy outcomes. Therefore, a follow-up evaluation 1 month after completion of treatment should be considered to evaluate whether therapy was effective.¹ **SOR C**
- If symptoms do recur, consider a treatment regimen different from the original regimen to treat recurrent disease.¹ **SOR C**

PATIENT EDUCATION

- Avoid consuming alcohol during treatment with metronidazole and for 24 hours thereafter. Women should be advised to return for additional therapy if symptoms recur because recurrence of BV is not unusual.

83 CANDIDA VULVOVAGINITIS

E.J. Mayeaux, Jr., MD
Richard P. Usatine, MD

PATIENT STORY

A 35-year-old woman presents with severe vaginal and vulvar itching. She also complains of a thick white discharge. **Figure 83-1** demonstrates the appearance of her vagina and cervix and **Figure 83-2** shows her vulva. **Figure 83-3** shows her wet prep. Treatment with a nonprescription intravaginal preparation was successful.

INTRODUCTION

Vulvovaginal candidiasis (VVC) is a common fungal infection in women of childbearing age. Pruritus is accompanied by a thick, odorless, white vaginal discharge. VVC is not a sexually transmitted disease. On the basis of clinical presentation, microbiology, host factors, and response to therapy, VVC can be classified as either uncomplicated or complicated.¹ Uncomplicated VVC is characterized by sporadic or infrequent symptoms, mild-to-moderate symptoms, and the patient is nonimmunocompromised. Complicated VVC is characterized by recurrent (four or more episodes in 1 year) or severe VVC, non-albicans candidiasis, or the patient has uncontrolled diabetes, debilitation, or immunosuppression.¹

SYNONYMS

Yeast vaginitis, yeast infection, candidiasis, moniliasis.

EPIDEMIOLOGY

- VVC accounts for approximately one third of vaginitis cases.¹
- *Candida* species are part of the lower genital tract flora in 20% to 50% of healthy asymptomatic women.²
- Seventy-five percent of all women in the United States will experience at least one episode of VVC. Of these, 40% to 45% will have two or more episodes within their lifetime.³ Approximately 10% to 20% of women will have complicated VVC that necessitates diagnostic and therapeutic considerations.
- It is a frequent iatrogenic complication of antibiotic treatment, secondary to altered vaginal flora.
- Nearly half of all women experience multiple episodes, and up to 5% experience recurrent disease.¹
- Recurrent vulvovaginal candidiasis (RVVC) is defined as four or more episodes of symptomatic VVC in 1 year. It affects a small percentage of women (<5%).⁴ Recurrent yeast vaginitis is usually caused by relapse, and less often by reinfection. Recurrent infection may be caused by *Candida* recolonization of the vagina from the rectum.⁵

FIGURE 83-1 *Candida* on the vulva and introitus showing whitish patches with erythema. (Courtesy of Richard P. Usatine, MD.)

FIGURE 83-2 *Candida* vaginitis. Note the thick white adherent "cottage-cheese-like" discharge. (Courtesy of the Centers for Disease Control and Prevention and Stuart Brown, MD.)

ETIOLOGY AND PATHOPHYSIOLOGY

- Most vulvovaginal Candidiasis is caused by *Candida albicans* (Figure 83-3).^{1,6} *Candida glabrata* now causes a significant percentage of all *Candida* vulvovaginal infections. This organism is resistant to the nonprescription imidazole creams. It can mutate out of the activity of treatment drugs much faster than *albicans* species.⁷
- The disease is suggested by pruritus in the vulvar area, together with erythema of the vagina and vulva (Figures 83-1 and 83-2). The familiar reddening of the vulvar tissues is caused by an ethanol by-product of the *Candida* infection. This ethanol compound also produces pruritic symptoms. A scalloped edge with satellite lesions is characteristic of the erythema on the vulva.
- VVC can occur concomitantly with sexually transmitted diseases (STDs).
- The pathogenesis of recurrent VVC is poorly understood, and most women with these recurrences have no apparent predisposing or underlying conditions.¹

RISK FACTORS^{8,9}

- Diabetes mellitus.
- Recent antibiotic use.
- Increased estrogen levels.
- Immunosuppression.
- Contraceptive devices (vaginal sponges, diaphragms, and intrauterine devices).
- Genetic susceptibility.
- Behavioral factors—VVC may be linked to orogenital and, less commonly, anogenital sex.
- Wearing diapers.
- Spermicides are **not associated** with *Candida* infection.
- There is no high-quality evidence showing a link between VVC and hygienic habits or wearing tight or synthetic clothing.

DIAGNOSIS

CLINICAL FEATURES

- The diagnosis is usually suspected by characteristic findings (Figures 83-1 and 83-2). Typical symptoms include pruritus, vaginal soreness, dyspareunia, and external dysuria. Typical signs include vulvar edema, fissures, excoriations, or thick, curdy vaginal discharge.¹

LABORATORY TESTING (INCLUDE ANCILLARY TESTING TOO)

- Vaginitis solely caused by *Candida* generally has a normal vaginal pH of less than 4.5.
- The wet prep, KOH smear, or Gram stain may demonstrate yeast and/or pseudohyphae (Figures 83-3 and 83-4). Wet preps may

FIGURE 83-3 Wet mount with KOH of *Candida albicans* in a woman with *Candida* vaginitis. Seen under high power demonstrating branching pseudohyphae and budding yeast. (Courtesy of Richard P. Usatine, MD.)

FIGURE 83-4 Wet mount with saline showing *Candida* in a woman with *Candida* vaginitis. Note how the branching pseudohyphae and budding yeast can be seen even though the epithelial cells have not been lysed by KOH. (Courtesy of Richard P. Usatine, MD.)

also demonstrate white blood cells, trichomonads, candidal hyphae, or clue cells.

- The KOH prep is made by adding a drop of KOH solution to a drop of saline suspension of the discharge. The KOH lyses epithelial cells in 5 to 15 minutes (faster if the slide is warmed) and allows easier visualization of candidal hyphae or yeast.¹ Swartz-Lamkins stain (potassium hydroxide, a surfactant, and blue dye) may facilitate diagnosis by staining the yeast organisms a light blue.¹⁰
- Rapid antigen testing is also available for *Candida*. The detection of vaginal yeast by rapid antigen testing is feasible for office practice and more sensitive than wet mount. A negative test result, however, was not found to be sensitive enough to rule out yeast and avoid a culture.⁶ **SOR A**
- Fungal culture with Sabouraud agar, Nickerson medium, or Microstix-*Candida* medium should be considered in patients with symptoms and a negative KOH because *C. glabrata* does not form pseudohyphae or hyphae and is not easily recognized on microscopy. If the wet mount is negative and *Candida* cultures cannot be done, empiric treatment can be considered for symptomatic women with any sign of VVC on examination.¹ **SOR C** Asymptomatic women should not be cultured as 10% to 20% of women harbor *Candida* sp. and other yeasts in the vagina.¹ **SOR A**
- Vaginal cultures should be obtained from patients with RVVC to confirm the clinical diagnosis and to identify unusual species, including non-*albicans* species, particularly *C. glabrata* (*C. glabrata* does not form pseudohyphae or hyphae and is not easily recognized on microscopy).¹ **SOR B** *C. glabrata* and other non-*albicans* *Candida* species are observed in 10% to 20% of patients with RVVC.¹
- Given the frequency at which RVVC occurs in the immunocompetent healthy population, the occurrence of RVVC alone should not be considered an indication for HIV testing.¹ **SOR C**

DIFFERENTIAL DIAGNOSIS

- Trichomoniasis can be confused with candidiasis because patients may report itching and a discharge in both diagnoses. Look for the strawberry cervix on examination and moving trichomonads on the wet prep (Chapter 84, *Trichomonas* Vaginitis).
- Bacterial vaginosis can be confused with candidiasis because patients may report a discharge and an odor in both diagnoses. The odor is usually much worse in bacterial vaginosis and the quality of the discharge can be different. The wet prep should allow for differentiation between these two infections (Chapter 82, Bacterial Vaginosis).
- Gonorrhea and *Chlamydia* should not be missed in patients with vaginal discharge. Consider testing for these STDs based on patients' risk factors and the presence of purulence clinically and white blood cells on the wet prep (Chapter 85, *Chlamydia* Cervicitis).
- Cytolytic vaginosis, or Döderlein cytolysis, can be confused with candidiasis. Cytolytic vaginosis is produced by a massive desquamation of epithelial cells related to excess lactobacilli in the vagina. The signs and symptoms are similar to *Candida* vaginitis, except no yeast are found on wet prep. The wet prep will show an overgrowth

of lactobacilli. The treatment is to discontinue all antifungals and other agents or procedures that alter the vaginal flora.

MANAGEMENT

NONPHARMACOLOGIC

- VVC is not usually acquired through sexual intercourse; treatment of sex partners is not recommended but may be considered in women who have recurrent infection. Some male sex partners might have balanitis (Chapter 136, Candidiasis) and might benefit from treatment.¹ **SOR A**
- Any woman whose symptoms persist after using a nonprescription preparation or who has a recurrence of symptoms within 2 months should be evaluated with office-based testing as they are not necessarily more capable of diagnosing themselves even with prior diagnosed episodes of VVC and delay in the treatment of other vulvovaginitis etiologies can result in adverse clinical outcomes.¹ **SOR A**

MEDICATIONS

- Women with typical symptoms and a positive test result should receive treatment. Short-courses of topical formulations effectively treat uncomplicated VVC (**Table 83-1**).¹ **SOR A** Topical azole drugs are more effective than nystatin, and result in clinical cure and negative cultures in 80% to 90% of patients who complete therapy. **SOR A** The creams and suppositories in **Table 83-1** are oil-based and might weaken latex condoms and diaphragms.¹
- The cure rates with single-dose oral fluconazole and all the intravaginal treatments are equal.¹¹ Fluconazole (Diflucan) 150-mg single dose has become very popular, but may have clinical cure rates of approximately only 70%. **SOR A** Systemic allergic reactions are possible with the oral agents.
- The oral agents fluconazole, ketoconazole, and itraconazole also appear to be effective.¹ **SOR B**
- VVC frequently occurs during pregnancy. Only topical azole therapies, applied for 7 days, are recommended for use among pregnant women.¹ **SOR C**
- The optimal treatment of non-*albicans* VVC remains unknown. Options include longer duration of therapy (7 to 14 days) with topical therapy or a 100-mg, 150-mg, or 200-mg oral dose of fluconazole every third day for a total of 3 doses.¹ **SOR C**
- Severe VVC (i.e., extensive vulvar erythema, edema, excoriation, and fissure formation) is associated with lower clinical response rates in patients treated with short courses of topical or oral therapy. Either 7 to 14 days of topical azole or 150 mg of fluconazole in two sequential doses (second dose 72 hours after initial dose) is recommended.¹ **SOR C**

COMPLEMENTARY AND ALTERNATIVE THERAPY

- If recurrence VVC occurs, 600 mg of boric acid in a gelatin capsule is recommended, administered vaginally once daily for 2 weeks. This regimen has clinical and mycologic eradication rates of approximately 70%.¹ **SOR B**

TABLE 83-1 Centers for Disease Control and Prevention Recommended Treatment Regimens

Intravaginal Agents:

- Butoconazole** 2% cream 5 g intravaginally for 3 days
- Butoconazole** 2% cream 5 g (Butaconazole1-sustained release), single intravaginal application*
- Clotrimazole** 1% cream 5 g intravaginally for 7 to 14 days
- Clotrimazole** 2% cream 5 g intravaginally for 3 days
- Clotrimazole** 100 mg vaginal suppositories, one intravaginally for 3 days
- Miconazole** 2% cream 5 g intravaginally for 7 days
- Miconazole** 100 mg vaginal suppository, 1 suppository for 7 days
- Miconazole** 200 mg vaginal suppository, 1 suppository for 3 days
- Miconazole** 1200 mg vaginal suppository, 1 suppository for 1 day
- Nystatin** 100,000-U vaginal tablet, 1 tablet for 14 days*
- Tioconazole** 6.5% ointment 5 g intravaginally in a single application
- Terconazole** 0.4% cream 5 g intravaginally for 7 days*
- Terconazole** 0.8% cream 5 g intravaginally for 3 days*
- Terconazole** 80 mg vaginal suppository, 1 suppository for 3 days*

Oral Agent:

- Fluconazole** 150-mg oral tablet, 1 tablet in single dose*

*Prescription only in the United States.

Data from the Centers for Disease Control and Prevention.¹

- *Lactobacillus acidophilus* does not adhere well to the vaginal epithelium, and it does not significantly change the incidence of candidal vulvovaginitis.^{5,12}
- There is no evidence from randomized trials that other complementary and alternative (CAM) therapies, such as garlic, tea tree oil, yogurt, or douching, are effective for the treatment or prevention of VVC caused by *C. albicans*.^{13,14}

PREVENTION

MAINTENANCE REGIMENS

- Oral fluconazole (i.e., 100-mg, 150-mg, or 200-mg dose) weekly for 6 months is the first line of treatment. If this regimen is not feasible, some specialists recommend topical clotrimazole 200 mg twice a week, clotrimazole (500-mg dose vaginal suppositories once weekly), or other topical treatments used intermittently.¹ **SOR C**
- Suppressive maintenance antifungal therapies are effective in reducing RVVC.¹ **SOR A** However, 30% to 50% of women will have recurrent disease after maintenance therapy is discontinued. Routine treatment of sex partners is controversial. *C. albicans* azole resistance is rare in vaginal isolates, and susceptibility testing is usually not warranted for individual treatment guidance.

PROGNOSIS

- Women with underlying debilitating medical conditions (e.g., those with uncontrolled diabetes or those receiving corticosteroid treatments) do not respond as well to short-term therapies. Efforts to correct modifiable conditions should be made, and more prolonged (i.e., 7 to 14 days) conventional antimycotic treatment is necessary.¹ **SOR C**
- Symptomatic VVC is more frequent in HIV-seropositive women and correlates with severity of immunodeficiency. In addition, among HIV-infected women, systemic azole exposure is associated with the isolation of non-*C. albicans* species from the vagina. According to the available data, therapy for VVC in HIV-infected women should not differ from that for seronegative women.¹ **SOR C**

FOLLOW-UP

- Patients should be instructed to return for follow-up visits only if symptoms persist or recur within 2 months of onset of initial symptoms.¹

PATIENT EDUCATION

- Studies show that women who were previously diagnosed with VVC are not necessarily more likely to be able to diagnose themselves.¹ Any woman whose symptoms persist after using a non-prescription preparation, or who has a recurrence of symptoms within 2 months, should be evaluated with office-based testing. Explain that unnecessary or inappropriate use of nonprescription preparations can lead to a delay in the treatment of other vulvovaginitis etiologies, which can result in adverse clinical outcomes.¹

84 TRICHOMONAS VAGINITIS

E.J. Mayeaux Jr., MD
Richard P. Usatine, MD

PATIENT STORY

A 27-year-old woman presents with a vaginal itching, odor, and discharge for 1 week. She has one partner who is asymptomatic. Speculum examination shows a strawberry cervix seen with *Trichomonas* infections (**Figure 84-1**). This strawberry pattern is caused by inflammation and punctate hemorrhages on the cervix. There is a scant white discharge with a fishy odor. Wet mount shows trichomonads swimming in saline (**Figures 84-2 and 84-3**). The trichomonads are larger than white blood cells (WBCs) and have visible flagella and movement. She is diagnosed with trichomoniasis and treated with 2 g of metronidazole in a single dose. The patient is tested for other sexually transmitted diseases (STDs) and her partner is treated with the same regimen.

INTRODUCTION

Trichomonas vaginitis is a local infection caused by the protozoan *Trichomonas vaginalis* that is associated with vaginal discharge. The woman often has an itch and an odor along with the discharge but may be asymptomatic.

SYNONYMS

Trichomoniasis, trich, tricky monkeys.

EPIDEMIOLOGY

- An estimated 3 to 5 million cases of trichomoniasis occur each year in the United States.¹
- The worldwide prevalence of trichomoniasis is estimated to be 180 million cases per year; and these cases account for 10% to 25% of all vaginal infections.²

ETIOLOGY AND PATHOPHYSIOLOGY

- *Trichomonas* infection is caused by the unicellular protozoan *T. vaginalis*.³
- The majority of men (90%) infected with *T. vaginalis* are asymptomatic, but many women (50%) report symptoms.⁴
- The infection is predominantly transmitted via sexual contact. The organism can survive up to 48 hours at 10°C (50°F) outside the body, making transmission from shared undergarments or from infected hot spas possible although extremely unlikely.

FIGURE 84-1 Speculum examination showing the strawberry cervix pattern seen with *Trichomonas* infections. This strawberry pattern is caused by inflammation and punctate hemorrhages on the cervix. There is a scant white discharge. (Courtesy of Richard P. Usatine, MD.)

FIGURE 84-2 Wet mount showing *Trichomonas* in saline under low power. There are two visible trichomonads to the right and above the tip of the pointer. The largest cells are vaginal epithelial cells with visible nuclei. (Courtesy of Richard P. Usatine, MD.)

- *Trichomonas* infection is associated with low-birth-weight infants, premature rupture of membranes, and preterm delivery in pregnant patients.⁵
- In a person coinfecting with HIV, the pathology induced by *T. vaginalis* infection can increase HIV shedding. *Trichomonas* infection may also act to expand the portal of entry for HIV in an HIV-negative person. Studies from Africa have suggested that *T. vaginalis* infection may increase the rate of HIV transmission by approximately two-fold.⁶

RISK FACTORS³

- New or multiple partners.
- A history of STDs.
- Exchanging sex for payment or drugs.
- Injection drug use.

DIAGNOSIS

CLINICAL FEATURES

- The physical examination should include inspection of the external genitalia for irritation or discharge. Speculum examination is done to determine the amount and character of the discharge and to look for the characteristic strawberry cervix (**Figures 84-1 and 84-3**).
- Typically, women with trichomoniasis have a diffuse, malodorous, yellow-green discharge (**Figure 84-4**) with vulvar irritation.³ Vaginal and vulvar itching and irritation are common.
- It should be determined whether the patient douched recently, because this can lower the yield of diagnostic tests. Patients who have been told not to douche will sometimes start wiping the vagina with soapy washcloths to “keep clean” as an alternative. This greatly irritates the vagina and cervix, lowers test sensitivity, and may cause a discharge.

TYPICAL DISTRIBUTION

- In women, *Trichomonas vaginalis* may be found in the vagina, urethra, and paraurethral glands of infected women. Other sites include the cervix and Bartholin and Skene glands.

LABORATORY TESTING

- Because of the high prevalence of trichomoniasis, testing should be performed in women seeking care for vaginal discharge. Screening should be considered for women with risk factors.³
- Wet preps are obtained using a cotton-tipped applicator applied to the vaginal side-wall, placing the sample of discharge into normal saline (not water). A drop of the suspension is then placed on a slide, covered with a coverslip, and carefully examined with the low-power and high-dry objective lenses. Under the microscope, observe for motile trichomonads, which are often easy to visualize because of their lashing flagella (**Figure 84-2**).
- Wet prep has a sensitivity of only approximately 60% to 70% and requires immediate evaluation of wet preparation slide for optimal results.³
- The OSOM *Trichomonas* Rapid Test and the Affirm VP III are FDA-cleared for trichomoniasis in women. Both tests are performed

FIGURE 84-3 Wet mount showing *Trichomonas* (arrows) in saline under high power. The smaller more granular cells are white blood cells. (Courtesy of Richard P. Usatine, MD.)

FIGURE 84-4 Close-up of strawberry cervix in a *Trichomonas* infection demonstrating inflammation and punctate hemorrhages. (Courtesy of Richard P. Usatine, MD.)

on vaginal secretions at the point of care and have a sensitivity greater than 83% and a specificity greater than 97%. The results of the OSOM *Trichomonas* Rapid Test are available in approximately 10 minutes, and results of the Affirm VP III are available within 45 minutes. False-positive tests might occur, especially in populations with a low prevalence of disease.³

- An FDA-approved polymerase chain reaction (PCR) assay for detection of gonorrhea and chlamydial infection (Amplicor, manufactured by Roche Diagnostic Corp.) has been modified to test for *T. vaginalis* in vaginal or endocervical swabs and in urine from women and men, with sensitivity ranges from 88% to 97% and specificity from 98% to 99%.⁷
- APTIMA *T. vaginalis* Analyte Specific Reagents (ASR; manufactured by Gen-Probe, Inc.) also can detect *T. vaginalis* RNA using the same instrumentation platforms available for the FDA-cleared APTIMA Combo2 assay for diagnosis of gonorrhea and chlamydial infection. Published validation studies found sensitivity ranging from 74% to 98% and specificity from 87% to 98%.⁸
- A vaginal pH above 4.5 is seen with menopausal patients, *Trichomonas* infection, or bacterial vaginosis.⁴
- Culture is a sensitive and highly specific method of diagnosis. In women in whom trichomoniasis is suspected but not confirmed by microscopy, vaginal secretions should be cultured for *T. vaginalis*.³
- A nucleic acid amplification test for *Neisseria gonorrhoeae*, and/or *Chlamydia trachomatis* should be performed on all patients with *Trichomonas*.

DIFFERENTIAL DIAGNOSIS

- Bacterial vaginosis and *Trichomonas* may have the odor of aromatic amines, and therefore may easily be confused with each other. Look for clue cells and trichomonads on the wet prep to differentiate between the two (Chapter 82, Bacterial Vaginosis).
- *Candida* vaginitis tends to present with a cottage-cheese-like discharge and vaginal itching (Chapter 83, *Candida* Vaginitis).
- Gonorrhea and *Chlamydia* and should not be missed in patients with vaginal discharge. Consider testing for these STDs based on patients' risk factors and the presence of purulence clinically and WBCs on the wet prep (Chapter 85, *Chlamydia* Cervicitis).

MANAGEMENT

MEDICATIONS

- **Table 84-1** shows treatments for *T. vaginalis* infections. Metronidazole 2 g orally as a single dose, or 500 mg bid for 7 days (including pregnant patients) are the best treatments by Cochrane analysis.⁹ **SOR A**
- Tinidazole (Tindamax), a second-generation nitroimidazole, is indicated as a one-time dose of 2 g for the treatment of trichomoniasis (including metronidazole-resistant trichomoniasis).³ **SOR A** It is effective therapy in nonresistant and resistant *T. vaginalis*.^{10,11} The contraindications (including ethyl alcohol [ETOH]) to the use of tinidazole are similar to those for metronidazole.
- Pregnant women may be treated with 2 g of metronidazole in a single dose. Metronidazole is pregnancy category B. Vaginal

FIGURE 84-5 Speculum examination demonstrating the thick yellow-green discharge that may be seen in *Trichomonas* infection. The discharge can also be frothy white. (Courtesy of E.J. Mayeaux, Jr., MD.)

TABLE 84-1 Centers for Disease Control and Prevention Recommended Regimens for Pregnant and Nonpregnant Patients. **SOR A**

Metronidazole 2 g orally in a single dose

OR

Tinidazole 2 g orally in a single dose

CDC Alternative Regimen **SOR A**

Metronidazole 500 mg orally twice a day for 7 days

Data from Centers for Disease Control and Prevention.^{2,3}

trichomoniasis is associated with adverse pregnancy outcomes, particularly premature rupture of membranes, preterm delivery, and low birth weight. Unfortunately, data do not suggest that metronidazole treatment results in a reduction in perinatal morbidity and treatment may even increase prematurity or low birth weight.³ Treatment of *T. vaginalis* might relieve symptoms of vaginal discharge in pregnant women and might prevent respiratory or genital infection of the newborn and further sexual transmission. The Centers for Disease Control and Prevention (CDC) recommends that clinicians counsel patients regarding the potential risks and benefits of treatment during pregnancy.³

- Some strains of *T. vaginalis* can have diminished susceptibility to metronidazole. Low-level metronidazole resistance has been identified in 2% to 5% of cases of vaginal trichomoniasis. These infections should respond to tinidazole or higher doses or longer durations of metronidazole. High-level resistance is rare.
- Metronidazole gel is 50% less efficacious for the treatment of trichomoniasis than oral preparations and is not recommended.³

PREVENTION

- Patients should be instructed to avoid sex until they and their sex partners are cured (i.e., when therapy has been completed and patient and partner[s] are asymptomatic).³
- Spermicidal agents such as nonoxynol-9 reduce the rate of transmission of *Trichomonas*.¹²
- The risk of acquiring infection can be reduced by consistent use of condoms and limiting the number of sexual partners.

FOLLOW-UP

- Because of the high rate of reinfection among patients in whom trichomoniasis was diagnosed, rescreening at 3 months following initial infection can be considered for sexually active women.³

PATIENT EDUCATION

- Sexual partners of patients with *Trichomonas* should be treated. Patients can be sent home with a dose for a partner when it is believed that the partner will not come in on his own.

85 CHLAMYDIA CERVICITIS

E.J. Mayeaux, Jr., MD
Richard P. Usatine, MD

PATIENT STORY

A 17-year-old girl presents to the sexually transmitted disease (STD) clinic because her boyfriend was diagnosed with a *Chlamydia* urethritis. Both she and her boyfriend admit to having had sexual partners in the past before starting to be sexually active with each other. On physical examination, there is ectopy and some mucoid discharge (**Figure 85-1**). The cervix bled easily while obtaining discharge and cells for a wet mount and genetic probe test. The wet mount showed many white blood cells (WBCs) but no visible pathogens. The patient was treated with 1 g of azithromycin taken in front of a clinic nurse. She was sent to the laboratory for rapid plasma reagin (RPR) and HIV tests and given a follow-up appointment in 1 week. The genetic probe test was positive for *Chlamydia* and all the other examinations were negative. This information was given to the patient on her return visit and safe sex was discussed.

INTRODUCTION

Chlamydia trachomatis causes genital infections that can result in pelvic inflammatory disease (PID), ectopic pregnancy, and infertility. Asymptomatic infection is common among both men and women so healthcare providers must rely on screening tests to detect disease. The Centers for Disease Control and Prevention (CDC) recommends annual screening of all sexually active women ages 25 years and younger, and of older women with risk factors, such as having a new sex partner or multiple sex partners.¹

EPIDEMIOLOGY

- A very common STD, *Chlamydia* is the most frequently reported infectious disease in the United States (excluding human papillomavirus [HPV]).¹ An estimated 1.2 million cases are reported to the CDC annually in the United States.²
- The World Health Organization (WHO) estimates there are 140 million cases of *Chlamydia trachomatis* infection worldwide every year.³
- The CDC estimates screening and treatment programs can be conducted at an annual cost of \$175 million. Every dollar spent on screening and treatment saves \$12 in complications that result from untreated *Chlamydia*.⁴
- It is common among sexually active adolescents and young adults.⁵ As many as 1 in 10 adolescent girls tested for *Chlamydia* is infected. Based on reports to the CDC provided by states that collect age-specific data, teenage girls have the highest rates of chlamydial infection. In these states, 15- to 19-year-old girls represent 46% of infections and 20- to 24-year-old women represent another 33%.⁴

FIGURE 85-1 Chlamydial cervicitis with ectopy, mucoid discharge, and bleeding. The cervix is inflamed and friable. (Courtesy of Connie Celum and Walter Stamm, Seattle STD/HIV Prevention Training Center, University of Washington.)

ETIOLOGY AND PATHOPHYSIOLOGY

- *C. trachomatis* is a small Gram-negative bacterium with unique biologic properties among living organisms. *Chlamydia* is an obligate intracellular parasite that has a distinct life-cycle consisting of two major phases: The small elementary bodies attach and penetrate into cells, and the metabolically active reticulate bodies that form large inclusions within cells.
- It has a long growth cycle, which explains why extended courses of treatment are often necessary. Immunity to infection is not long-lived, so reinfection or persistent infection is common.
- The infection may be asymptomatic and the onset often indolent. It can cause cervicitis, endometritis, PID, urethritis, epididymitis, neonatal conjunctivitis, and pediatric pneumonia. Of exposed babies, 50% develop conjunctivitis and 10% to 16% develop pneumonia.¹
- *Chlamydia* infections may lead to reactive arthritis, which presents with arthritis, conjunctivitis, and urethritis (Chapter 155, Reactive Arthritis). Past or ongoing *C. trachomatis* infection may be a risk factor for ovarian cancer.^{6,7}
- Up to 40% of women with untreated *Chlamydia* will develop PID. Undiagnosed PID caused by *Chlamydia* is common. Of those with PID, 20% will become infertile; 18% will experience debilitating, chronic pelvic pain; and 9% will have a life-threatening tubal pregnancy. Tubal pregnancy is the leading cause of first-trimester, pregnancy-related deaths in American women.⁴

RISK FACTORS^{1,2,8}

- Adolescents and young adults.
- Nonwhite populations.
- Multiple sexual partners.
- Poor socioeconomic conditions.
- Single marital status.
- Nonbarrier contraceptive use.
- History of prior STD.

DIAGNOSIS

CLINICAL FEATURES

- The cervix is inflamed, friable, and may bleed easily with manipulation. The cervix may show ectopy (columnar cells on the ectocervix). The discharge is usually mucoid or mucopurulent (**Figure 85-1**).
- Swab test—A white cotton-tip applicator is placed in the endocervical canal and removed to view. A visible mucopurulent discharge constitutes a positive swab test for *Chlamydia* (**Figure 85-2**). This is not specific for *Chlamydia* as other genital infections can cause a mucopurulent discharge, and is not recommended for diagnosis.

LABORATORY TESTING

- A significant proportion of patients with *Chlamydia* are asymptomatic, providing a reservoir for infection. All pregnant women and

FIGURE 85-2 Mucopurulent discharge on the left swab from a cervix infected with *Chlamydia* (positive swab test). (Courtesy of Claire Stevens and Ronald Roddy, Seattle STD/HIV Prevention Training Center, University of Washington.)

sexually active women younger than 25 years of age should be screened with routine examinations. A wet prep is usually negative for other organisms. Only WBCs and normal flora are seen.

- *Chlamydia* cannot be cultured on artificial media because it is an obligate intracellular organism. Tissue culture is required to grow the live organism. When testing for *Chlamydia*, a wood-handled swab must not be used, as substances in wood may inhibit *Chlamydia* organism. Culture has sensitivity of 70% to 100% and a specificity of almost 100%, which makes it the gold standard.¹
- The enzyme-linked immunosorbent assay (ELISA) technique (Chlamydiazyme) has a sensitivity of 70% to 100% and a specificity of 97% to 99%.⁵ Fluorescein-conjugated monoclonal antibodies test (MicroTrak) has a sensitivity of 70% to 100% and a specificity of 97% to 99%.⁵
- *C. trachomatis* can be detected using nucleic acid amplification techniques (NAATs) on swabs or voided urine specimens. These tests are often used for testing to detect gonorrhea and *Chlamydia*. Nucleic acid amplification tests have been used successfully in difficult-to-reach adolescents (“street kids”) as well as in pediatric emergency departments and school-based settings.^{9,10} Screening in school-based settings was associated with significant reduction in *Chlamydia* rates during a 1-year period. Self-collected vaginal swab specimens perform at least as well as with other approved specimens using NAATs.¹¹
- Rectal and oropharyngeal *C. trachomatis* infection in persons engaging in anal or oral intercourse can be diagnosed by testing at the site of exposure. Although not FDA-cleared for this use, NAATs have demonstrated improved sensitivity and specificity compared with culture for the detection at rectal sites¹² and at oropharyngeal sites in men.¹³
- Certain NAATs have been FDA-cleared for use on liquid-based cytology specimens, although test sensitivity using these specimens might be lower.¹⁴
- Persons who undergo testing for *Chlamydia* should be tested for other STDs as well.¹

DIFFERENTIAL DIAGNOSIS

- Gonorrhea frequently coexists with *Chlamydia* and should be tested for when a patient is thought to have *Chlamydia*. The discharge of gonorrhea may be more purulent but this is not always the case (Chapter 215, Gonococcal Urethritis)
- Bacterial vaginosis—The aromatic amine odor and clue cells help to distinguish between these infections (Chapter 82, Bacterial Vaginosis).
- Trichomoniasis—Look for the strawberry cervix and *Trichomonas* on the wet prep. There may also be a positive whiff test (see Chapter 84, *Trichomonas* Vaginitis).

MANAGEMENT

NONPHARMACOLOGIC

- Patients diagnosed with *Chlamydia* cervicitis should be tested for other STDs.¹

TABLE 85-1 Centers for Disease Control and Prevention Recommended Regimens **SOR A**

Azithromycin 1 g orally in a single dose

OR

Doxycycline 100 mg orally twice a day for 7 days

CDC Alternative Regimens

Erythromycin base 500 mg orally 4 times a day for 7 days

OR

Erythromycin ethylsuccinate 800 mg orally 4 times a day for 7 days

OR

Ofloxacin 300 mg orally twice a day for 7 days

OR

Levofloxacin 500 mg orally once daily for 7 days

CDC Recommended Regimens in Pregnancy

Azithromycin 1 g orally in a single dose

OR

Amoxicillin 500 mg orally 3 times a day for 7 days

Alternative Regimens in Pregnancy

Erythromycin base 500 mg orally 4 times a day for 7 days

OR

Erythromycin base 250 mg orally 4 times a day for 14 days

OR

Erythromycin ethylsuccinate 800 mg orally 4 times a day for 7 days

OR

Erythromycin ethylsuccinate 400 mg orally 4 times a day for 14 days

Data from the Centers for Disease Control and Prevention.¹**MEDICATIONS**

- **Table 85-1** shows CDC recommended treatments for *Chlamydia*. Azithromycin (Zithromax) 1000 mg one-time dose is easy and may be directly observed in the clinic.¹ **SOR A** It is the first-line therapy for *Chlamydia* during pregnancy.
- Other treatments include doxycycline 100 mg PO bid × 7 days.¹ **SOR A** Avoid dairy products around time of dosing.
- Erythromycin might be less efficacious than either azithromycin or doxycycline, mainly because of the frequent occurrence of GI side effects that can lead to nonadherence.
- Ofloxacin (Floxin) 300 mg po bid × 7 days is an alternative that should be taken on an empty stomach.¹ **SOR A** It is contraindicated in children or pregnant and lactating women, but may also cover

Neisseria gonorrhoeae infection. Levofloxacin 500 mg orally for 7 days is another fluoroquinolone alternative.¹ **SOR A**

- A metaanalysis of 12 randomized clinical trials of azithromycin versus doxycycline for the treatment of genital chlamydial infection demonstrated that the treatments were equally efficacious, with microbial cure rates of 97% and 98%, respectively.¹⁵
- Partners need treatment. If concerns exist that sex partners will not seek evaluation and treatment, then delivery of antibiotic therapy (either a prescription or medication) to their partners is an option.¹
- Medications for chlamydial infections should be dispensed on site and the first dose directly observed to maximize medication adherence.¹

REFERRAL OR HOSPITALIZATION

- With evidence of complications such as a tuboovarian abscess or severe PID.

PREVENTION

- Individuals who are sexually active should be aware of the risk of STDs and that ways of avoiding infection include mutual monogamy and appropriate barrier protection.

PROGNOSIS

- Treatment failures with full primary therapies are quite rare. Reinfection is very common and is related to nontreatment of sexual partners or acquisition from a new partner.

FOLLOW-UP

- Test-of-cure (repeat testing 3 to 4 weeks after completing therapy) is not recommended for persons treated with the recommended or alternative regimens, unless therapeutic compliance is in question, symptoms persist, or reinfection is suspected. However, test of cure is recommended in pregnant women.¹

PATIENT EDUCATION

- To minimize transmission, persons treated for *Chlamydia* should be instructed to abstain from sexual intercourse for 7 days after single-dose therapy or until completion of a 7-day regimen.
- To minimize the risk for reinfection, patients also should be instructed to abstain from sexual intercourse until all of their sex partners are treated.¹

SECTION 3 VULVA

86 PAGET DISEASE OF THE
EXTERNAL GENITALIA

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 60-year-old woman presented with vulvar pruritus for 1 year that is now constant. On physical examination, there is one large red lesion surrounded by white epithelium (**Figure 86-1**). A 3-mm punch biopsy was done of the white island within the red lesion using local anesthesia. The pathology showed Paget disease of the vulva. The patient underwent a wide local excision of the involved area and no malignancy was found.

INTRODUCTION

Paget disease of the external genitalia is an uncommon primary cutaneous adenocarcinoma of apocrine gland-bearing skin. The most commonly involved site is the vulva, although perineal, perianal, scrotal, and penile skin may also be affected. Less commonly, the axilla, buttocks, thighs, eyelids, and external auditory canal may be found.¹ It is morphologically and histologically identical to Paget disease of the nipple except for the anatomic location.

SYNONYMS

Extramammary Paget disease.

EPIDEMIOLOGY

- The frequency of malignancy in extramammary Paget disease is approximately 20%, which is less than that of Paget disease of the nipple.
- It accounts for less than 5% of all vulvar malignancies.²
- The female-to-male ratio is 3 to 4.5 to 1.³
- Most patients are white and in their sixth or seventh decade of life.⁴
- Approximately 4% to 25% of patients with genital Paget disease have an underlying neoplasm.⁴⁻⁶ Associated malignancies include carcinomas of the Bartholin glands, urethra, bladder, vagina, cervix, endometrium, or adnexal apocrine tissue. Only a minority of cases represent a direct extension of an underlying carcinoma.
- Perianal Paget disease (**Figure 86-2**) is associated with underlying colorectal carcinoma in 25% to 35% of cases.

FIGURE 86-1 Paget disease of the vulva. Note the red lesion with the “white island.” (Courtesy of Hope Haefner, MD.)

ETIOLOGY AND PATHOPHYSIOLOGY

- It arises from apocrine gland tissue, usually as a primary cutaneous adenocarcinoma. The epidermis becomes infiltrated with neoplastic cells showing glandular differentiation. The tumor cells may originate from apocrine gland ducts or from keratinocytic stem cells.

RISK FACTORS

- Extramammary Paget disease should be considered in any patient with chronic dermatitis of the groin, vulva, scrotal, or perianal area. Patients with Paget disease of the external genitalia often present with nonresolving eczematous lesions in the groin, genitalia, perineum, or perianal area.⁷

DIAGNOSIS

CLINICAL FEATURES

- Lesions present on the vulva as geographic red macules that often appear excoriated or have an eczematoid appearance (**Figures 86-1 to 86-3**). The lesions are often dotted with small, white patches (islands of tissue). Other lesions may be erythematous, eczematous, or leukoplakic plaques (**Figure 86-4**).²
- Pruritus occurs in approximately 70% of patients.² Patients may also experience burning, pain, or no symptoms other than the lesion.⁶
- The lesions are well-demarcated and have slightly raised edges.
- Vulvar Paget disease is similar in gross appearance to Paget disease of the breast.

TYPICAL DISTRIBUTION

- It is usually multifocal and may occur anywhere on the vulva, mons, perineum, perianal area, inner thigh, nipple, or bladder. It occurs less often in males (**Figures 86-3 and 86-4**).

LABORATORY TESTING

- The appearance is similar to superficial melanoma, and sometimes special stains using markers that separate malignant melanocytes from Pagetoid cells may be necessary to identify the correct neoplasm.

IMAGING

- Imaging studies should be used to augment physical and endoscopic examination to assess possible undetected internal malignancy.

BIOPSY

- Biopsy of gross lesions must be performed to determine the diagnosis and the depth and nature of stromal invasion. A punch biopsy should be taken from the center of the lesion and include underlying dermis and connective tissue so the depth of stromal invasion can be determined. If multiple abnormal areas are present, then multiple biopsies should be taken.
- The diagnosis is made by identification of “pagetoid” cells in the epidermis.
 - These cells are round in shape and considerably larger than the surrounding keratinocytes or melanocytes.

FIGURE 86-2 Perianal Paget disease. Note the appearance is very similar to vulvar Paget disease. (Courtesy of University of Texas Health Sciences Center, Division of Dermatology.)

FIGURE 86-3 Paget disease of the scrotum. (Courtesy of University of Texas Health Sciences Center, Division of Dermatology.)

- The cytoplasm is pink and the nuclei are large, round, and have prominent nucleoli.
- The pagetoid cells cluster and form small nests in the rete pegs, but single cells spread into the superficial epidermis.

DIFFERENTIAL DIAGNOSIS^{2,8}

- Leukoplakia is an elevated white plaque seen before applying of acetic acid (see Chapter 87, Vulvar Intraepithelial Neoplasia).
- Squamous cell carcinoma of the vulva, which can appear as expanding ulcerative lesions but without the “white islands” (see Chapter 171, Squamous Cell Carcinoma).
- Hidradenitis suppurativa also tends to form in apocrine areas but usually presents as chronic recurring abscesses (see Chapter 115, Hidradenitis Suppurativa).
- Amelanotic melanoma of the vulva can occur, although vulvar melanoma is usually a pigmented lesion with irregular borders. Vulvar melanoma accounts for 5% of primary vulvar neoplasms, and occurs predominantly in postmenopausal white women (see Chapter 172, Melanoma).
- Condylomata acuminata (genital condylomas) are common and, when flat or excoriated, may be confused with vulvar Paget disease. More than one third of women have associated cervical intraepithelial neoplasia. Exophytic condylomas are typically verrucous, and usually occur in clusters along the vulvar surface (see Chapter 133, Genital Warts).
- Herpes simplex viruses 1 and 2 are associated with ulcerative genital lesions and characteristic systemic symptoms (see Chapter 129, Herpes Simplex).
- Fungal infections commonly affect the vulva and are usually caused by *Candida albicans*. Patients present with vulvar itching and burning. On inspection, the skin surface is red and may demonstrate small satellite lesions. A white “cottage cheese” discharge may also be present. Tinea cruris presents as a reddened area with raised sharp borders that occurs along the inner aspect of the thigh and often extends into the perianal and perineal region (see Chapter 136, Candidiasis).
- Lichen sclerosus is grossly and histologically similar to morphea (circumferential or localized scleroderma), which appears as white sclerotic or atrophic areas (**Figure 86-5**).
- Other dermatoses, including seborrheic or contact dermatitis, psoriasis, lichen planus, and lichen simplex chronicus, can resemble Paget disease when these conditions occur in the vulva or perineum.

MANAGEMENT

MEDICATIONS

- Topical imiquimod 5% cream applied 3 times weekly for 16 weeks has been shown to induce complete resolution in a patient with perineal disease.^{9,10} **SOR B** However, more studies are needed to define the exact role for this off-label therapy in this disease.

FIGURE 86-4 Paget disease of the scrotum and inguinal area. Note the white plaques with erythema that could be mistaken for *Candida* or tinea. (Courtesy of University of Texas Health Sciences Center, Division of Dermatology.)

FIGURE 86-5 Lichen sclerosus (et atrophicus) of vulva showing white sclerotic plaques and epidermal atrophy. This was biopsy proven to rule out Paget disease of the vulva and other possible malignancies. (Courtesy of Richard P. Usatine, MD.)

SURGICAL

- Treatment usually consists either of wide local excision with frozen sections or vulvectomy, if the disease is more extensive.^{2,5,6} **SOR B**
Local recurrence is common even in the face of negative surgical margins, presumably because the disease tends to be multicentric or from microscopic extension of disease beyond the margins.⁵
- Treatment with Mohs micrographic surgery may have a lower recurrence rate.⁸ **SOR B**
- The role of radiation therapy and chemotherapy (topical and systemic) in the treatment of vulvar Paget disease is not well-defined, but may be an option for some patients. **SOR C**

PROGNOSIS

- The prognosis for Paget disease of the external genitalia confined to the epidermis is excellent. The rate of invasive malignant conversion is low, and the cutaneous disease may extend over a period of 10 to 15 years without evidence of metastases. The prognosis depends mainly on the early diagnosis with definitive surgical treatment. Full recovery is possible in patients with purely epidermal disease and negative margins after micrographic surgery.
- Perianal disease, male genital disease, dermal invasion, and lymph node metastasis are poor prognostic indicators.²
- The recurrence rate of primary tumors after standard surgical excision is 30% to 60%. The rate after excision with Mohs micrographic surgery is 8% to 26%.^{8,11}

FOLLOW-UP

- Long-term follow-up is indicated because of the 8% to 60% risk of recurrence (even years after initial therapy) and the increased risk of noncontiguous carcinoma.^{8,11}
- The patient's vulva should be inspected annually and biopsy performed with any suggestion of abnormality.
- Screening and surveillance for tumors at other sites (breast, lung, colorectum, gastric, pancreas, and ovary) following national guidelines and U.S. Preventive Services Task Force guidelines should be considered.

87 VULVAR INTRAEPITHELIAL NEOPLASIA

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 63-year-old black woman presents with a “knot” on her labia majora (**Figures 87-1** and **87-2**). She is a smoker but is otherwise healthy. The lesion is occasionally pruritic but is generally asymptomatic. She found it approximately 6 months ago, and it has been slowly increasing in size. There is no significant family history of cancer. On physical exam she is found to have exophytic condyloma acuminata around the introitus and a growth labelled vulvar intraepithelial neoplasia (VIN) that the patient called a “knot.” A 3-mm punch biopsy is performed and demonstrates VIN III. The patient is referred to gynecologic oncology.

INTRODUCTION

Vulvar dysplasia and cancer is less common than cervical cancer. It is associated with high-risk human papillomavirus (HPV) infection, but not to the same extent as cervical disease.

EPIDEMIOLOGY

- Vulvar cancer is the fourth most common gynecologic cancer (following cancer of the endometrium, ovary, and cervix) and accounts for 5% of lower female genital tract malignancies.¹ There are approximately 3900 new cases and 870 deaths each year in the United States from this disease.¹
- Worldwide, vulvar cancer is rare, especially in developing countries. Approximately 27,000 cases are reported annually, making the incidence rate between 1 and 1.5 per 100,000 women.²
- Seventy-five percent of VIN cases occur in premenopausal women, with no racial predisposition.
- Although the rate of invasive vulvar carcinoma has remained stable in the past two decades, the incidence of in situ disease (VIN) has more than doubled. This may be the result of improved surveillance and treatment of VIN, or the apparent increase in cases of VIN in younger women.³

ETIOLOGY AND PATHOPHYSIOLOGY

- VIN is the associated preneoplastic condition that is associated with the loss of epithelial cell maturation and nuclear abnormalities.
- The cervix, vagina, vulva, anus, and lower 3 cm of rectal mucosa is derived from the embryonic cloaca. Most squamous intraepithelial lesions in this area affect multiple anatomic sites.
- HPV 16 is estimated to contribute to approximately 77% of VIN lesions.⁴

FIGURE 87-1 Patient with multiple exophytic condyloma and vulvar intraepithelial neoplasia III. The large clitoral hood is an incidental finding unrelated to the vulvar intraepithelial neoplasia. (Courtesy of Hope Haefner, MD.)

FIGURE 87-2 Close-up of the same patient with vulvar intraepithelial neoplasia III on the labia majora. (Courtesy of Hope Haefner, MD.)

- The risk of neoplastic progression appears to be lower with VIN than with cervical intraepithelial neoplasia. VIN I probably has minimal malignant potential, but VIN III often progresses to invasive cancer if left untreated (see “Biopsy” below).⁵

RISK FACTORS⁶

- Risk factors are similar to those for vaginal and cervical dysplasia:
 - High-risk HPV infection.
 - Cigarette smoking.
 - Altered immune status.

DIAGNOSIS

CLINICAL FEATURES

- The vulva is best examined using a good source of white light and magnification from a handheld magnifying lens or a colposcope. The examination should be systematic and incorporate all aspects of the vulvar surface. Vulvar examination may be aided by dilute acetic acid solution, which acts on the vulva much the same way as it does on the cervix and vagina. More acetic acid solution and a longer soaking time are required to achieve the acetowhite effect.
- VIN often appears as raised plaques and papules on the surface of the vulva and perineum (**Figures 87-1** and **87-2**).
- Approximately one quarter of these lesions are pigmented (usually brown).
- Fifty percent of VINs are white (leukoplakia) or become acetowhite after soaking with dilute acetic acid (**Figure 87-3**).
- Lesions may occasionally be red and ulcerate (**Figure 87-4**). White areas may also indicate malignant changes (**Figures 87-5** and **87-6**).
- VIN can appear warty, so lesions that are diagnosed as condyloma but do not respond to conservative therapy should be biopsied to rule out VIN.
- More than 50% of patients presenting with vulvar dysplasia are without symptoms. Of patients with symptoms, pruritus is the most common.
- Lesions may become confluent, involving the labia majora, minora, and perianal skin.

TYPICAL DISTRIBUTION

- Unlike cervical intraepithelial neoplasia, VIN is usually multifocal and can be located throughout the vulva, anus, and perineum. The interlabial grooves, posterior fourchette, and perineum are the most frequent locations (**Figures 87-1** to **87-6**).

BIOPSY

- Tissue biopsy is necessary for a definitive diagnosis of abnormal or ambiguous areas. After infiltration with lidocaine and epinephrine, 3-mm punch biopsies are performed in all suspicious areas. Bleeding can be stopped with a chemical hemostatic agent or electrocautery. Small biopsy sites usually do not need to be sutured and will heal well by secondary intention. Areas of ulceration should be sampled along the edge (**Figure 87-4**).

FIGURE 87-3 Diffuse white vulvar intraepithelial neoplasia III with ulceration. (Courtesy of Hope Haefner, MD.)

FIGURE 87-4 A small painful ulcer turned out to be vulvar intraepithelial neoplasia II on punch biopsy. A 3-mm punch biopsy was performed on the edge of the ulcer. (Courtesy of Richard P. Usatine, MD.)

- On histology, VIN may be graded as VIN I (mild dysplasia), VIN II (moderate dysplasia), or VIN III (severe dysplasia, carcinoma in situ) based upon the depth of epithelial involvement.
- VIN lesions are subdivided into three morphologic types: the basaloid type, which shows a thickened epithelium with a relatively flat, smooth surface; the warty type, which is characterized by a surface that has a condylomatous appearance; and the differentiated type, in which the epithelium is thickened and parakeratotic with elongated and anastomosing rete ridges.

DIFFERENTIAL DIAGNOSIS

- Micropapillae of the inner labia minora have commonly been misinterpreted as being secondary to HPV. Micropapillomatosis is a condition in which the vestibular papillae are atypically prominent. It is a benign normal variant.
- Sebaceous hyperplasia may be found as multiple small yellowish papules from Hart line (junction of the keratinized skin and mucosa) to the junction of the hair-bearing skin. This is a benign condition.
- HPV causes condylomata acuminata (genital condyloma). More than one third of women have associated cervical intraepithelial neoplasia. Exophytic condylomas are typically verrucous, and usually occur in clusters. They can be found at any site along the vulvar surface, and diagnosis is usually made by their characteristic appearance (see Chapter 133, Genital Warts).
- Herpes simplex viruses 1 and 2 produce grouped vesicles and ulcers, and are associated with genital lesions (see Chapter 129, Herpes Simplex).
- Molluscum contagiosum lesions appear as small papules with central umbilicated cores that contain a cheesy material (see Chapter 130, Molluscum Contagiosum).
- Secondary syphilis usually appears as a gray, plaque-like lesion (condyloma lata) (see Chapter 216, Syphilis).
- Granuloma inguinale produces small red lesions that appear from 3 weeks to 3 months after inoculation. These evolve into erosive ulcerations resulting in fibrosis and loss of superficial labial structures.
- Fungal infections commonly affect the vulva and are usually caused by *Candida albicans*. Patients present with vulvar itching and burning. On inspection, the skin surface is red and may demonstrate small satellite lesions. A white “cottage cheese” discharge may also be present (see Chapter 83, *Candida* Vulvovaginitis).
- Tinea cruris presents as a reddened area with raised sharp borders that occurs along the inner aspect of the thigh and often extends into the perianal and perineal region (see Chapter 139, Tinea Cruris).
- Lichen sclerosus is grossly and histologically similar to morphea (circumferential or localized scleroderma) and appears as white atrophic patches with erythema and loss of hair. Areas suspicious for VIN should be biopsied (**Figure 87-7**).
- Other dermatoses including psoriasis, lichen planus, and lichen simplex chronicus may present on the vulva and be confused with VIN.
- Nevi are benign melanocytic skin tumors that may occur in any area of the body, including the vulva.

FIGURE 87-5 A 59-year-old woman with long history of condyloma presents with a vaginal irritation. In addition to her cystocele after her hysterectomy, she is found to have *Trichomonas* and evidence of atrophic changes. However, the most concerning areas are the leukoplakia at the 6-, 11-, and 12-o'clock positions. These are most suspicious for vulvar intraepithelial neoplasia. (Courtesy of Richard P. Usatine, MD.)

FIGURE 87-6 The woman in **Figure 87-5** after punch biopsies are performed of the most suspicious areas. Both biopsies show moderate epithelial dysplasia, vulvar intraepithelial neoplasia II along with associated human papillomavirus changes. (Courtesy of Richard P. Usatine, MD.)

MANAGEMENT

NONPHARMACOLOGIC

- If the biopsy reveals condyloma, either observation or treatment with topical medications or surgical modalities (see Chapter 133, Genital Warts). Patients with VIN I can be followed by close observation.⁷ **SOR A**

MEDICATIONS

- 5-Fluorouracil (5-FU) cream has been a traditional treatment for VIN that causes a chemical desquamation of the lesion.⁸ It may result in significant burning, pain, inflammation, edema, and occasional painful ulcerations. Biopsy to exclude invasive disease is mandatory prior to 5-FU treatment.⁸ **SOR B**
- Imiquimod cream is a topical immune response modifier that is FDA-approved for the treatment of anogenital warts, actinic keratosis, and certain basal cell carcinomas.⁹ It has been used to treat multifocal VIN II or III in a few small pilot studies. The cream is self-administered 3 times per week for periods of 6 to 34 weeks.⁹ **SOR B**

SURGICAL

- Patients with VIN II or III should have their lesions removed. Basaloid and warty VINs may be treated with ablation on non-hair-bearing epithelium. CO₂ laser is most commonly performed, although some providers perform loop electrosurgical excision procedure.⁷ **SOR B**
- Differentiated VINs and any lesions in hair-bearing areas are generally treated with a wide local excision. Resected VIN specimens should be examined for residual disease in the margin.¹⁰ **SOR B**

PREVENTION

- The bivalent vaccine (Cervarix) containing HPV types 16 and 18 and the quadrivalent vaccine (Gardasil) vaccine containing HPV types 6, 11, 16, and 18 are effective at preventing VIN when given prophylactically. Vaccine efficacy against any VIN lesion (regardless of HPV type) in HPV-naïve patients was 75% (22% to 94%).¹¹

PROGNOSIS

- Surgical excision success is dependent upon margin status. Most recurrences will occur within 2 years.

FOLLOW-UP

- Because of the potential for disease persistence and recurrence, patients should be followed every 6 months for at least a year after treatment.⁷

FIGURE 87-7 A 55-year-old woman with lichen sclerosus (et atrophicus). A biopsy was taken at the site indicated by the arrow to confirm the diagnosis and make sure that there was no vulvar intraepithelial neoplasia arising in that area. (Courtesy of Richard P. Usatine, MD.)

PATIENT EDUCATION

- The diagnosis of high-grade dysplasia of the lower genital tract confers an increased risk of additional dysplasias and cancers for at least 20 years.¹² Continuing surveillance is necessary.

SECTION 4 COLPOSCOPY

88 COLPOSCOPY—NORMAL
AND NONCANCEROUS
FINDINGS

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 21-year-old woman presents for her well-woman examination. She has been followed by her physician for many years and has no complaints. She has been sexually active for a little more than 2 years with one mutually monogamous partner. She does not smoke, has never had a sexually transmitted disease (STD), and uses oral contraceptive pills for contraception. On speculum examination, her cervix appears normal (**Figure 88-1**) and a Papanicolaou (Pap) test is performed.

INTRODUCTION

The colposcope is an optical instrument using light and magnification that helps distinguish dysplasia and cervical cancer from benign cervical findings (**Figure 88-2**). Colposcopy (*colpo*: vagina; *scope*: to look) literally means to look into the vagina. Primary indications for colposcopy include certain abnormal Pap results or an abnormal appearing cervix. Colposcopically directed biopsies have a higher yield than biopsies done without the benefit of a colposcope, thereby decreasing the risk of false-negative biopsies.

SYNONYMS

Nabothian cysts are also called mucinous retention cysts or epithelial cysts.

An ectropion is also known as a persistent juvenile transformation zone or cervical erosion.

EPIDEMIOLOGY

- The Papanicolaou smear (Pap smear, Pap test) is a commonly employed screening test for dysplasia and cancer of the uterine cervix. More than 50 million Pap smears are performed each year in the United States.¹ The Pap test is a cytologic examination of cells taken from the cervical transformation zone (**Figures 88-3** and **88-4**). Colposcopy is the diagnostic test to evaluate patients with an abnormal cervical cytologic smear or abnormal-appearing cervix.
- Nabothian cysts are common and benign and are considered a normal feature of the adult cervix. They may occur singly or multiple cysts may be found simultaneously (**Figure 88-4**).²

FIGURE 88-1 Normal cervix as seen through a colposcope without the application of vinegar. The red color around the os is produced by columnar cells and the lighter pink on the remainder of the cervix result from normal squamous cells. The presence of visible columnar cells outside the internal os is called ectropion and is a normal finding in young women and women on estrogen-containing contraception. The junction between the two cell types and colors is the squamocolumnar junction. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 88-2 The family physician is looking at the cervix directly through the colposcope lenses and the image is also visible on the monitor for learners and/or the patient to see. (Courtesy of E.J. Mayeaux, Jr., MD.)

- Infections of the lower female genital tract are common and can produce a number of cervical epithelial changes (**Figure 88-5**).
- Cervical epithelial atrophy may occur in hypoenestrogenic states and cause the cervix to appear pale and the squamocolumnar junction to retract into the cervical os (**Figure 88-6**).
- Endocervical polyps are the most common benign neoplasms of the uterine cervix (**Figures 88-6 and 88-7**) and are most commonly found incidentally during pelvic examination. They are most common in the fourth to sixth decades of life and usually are asymptomatic, but may cause vaginal discharge or postcoital spotting.³ Most polyps are benign with the incidence of malignancy being approximately 1 in 1000.⁴

ETIOLOGY AND PATHOPHYSIOLOGY

- Colposcopy entails the use of a field microscope to examine the cervix. The cervix and vagina are examined under magnification, and all abnormal areas are identified.
- If the colposcopy is satisfactory, the entire transformation zone (TZ) is examined and the extent of all lesions is seen (**Figure 88-3**). Directed biopsies of the most abnormal areas are performed to obtain a tissue diagnosis.
- Colposcopy begins after visualization of the cervix prior to application of acetic acid to look for leukoplakia and abnormal vessels. Acetic acid 3% to 5% is applied with a cotton ball held in a ring forceps or with a rectal swab. Scan the cervix with low power (typically 5×) and determine if the entire TZ, including the entire squamocolumnar junction (SCJ) can be seen. The borders of all lesions must be entirely visible (not disappearing into the canal) for the examination to be adequate.
- Most of the normal cervical findings are derived from the physiologic transformation of the exposed columnar epithelium to squamous epithelium (**Figures 88-1 and 88-3**). Noncancerous findings may include epithelial thinning and whitening as a result of lack of estrogen, and polyp formations. The damage to the cervical epithelium from various infections often produces inflammation, friability, discharge, and bleeding.

DIAGNOSIS

CLINICAL FEATURES

- Normal colposcopic findings include:⁵
 - Original squamous epithelium, which is a featureless, smooth, pink epithelium without gland openings or nabothian cysts (**Figure 88-4**).
 - Columnar epithelium is a single-cell layer, mucous-producing epithelium that extends between the endometrium and the squamous epithelium. Columnar epithelium appears red and irregular with stromal papillae and clefts (**Figure 88-4**). With acetic acid application and magnification, columnar epithelium has a grape-like or “sea-anemone” appearance.
 - SCJ is a clinically visible line seen on the ectocervix or within the distal canal, which demarcates endocervical tissue from squamous (or squamous metaplastic) tissue (**Figure 88-4**).

FIGURE 88-3 Schematic demonstration of the development of the transformation zone. The transformation zone extends from the original (prepubertal) squamocolumnar junction to the new (current) squamocolumnar junction. This transformation zone in the area at highest risk for cervical cancer. (Courtesy of E.J. Mayeaux, Jr., MD.)

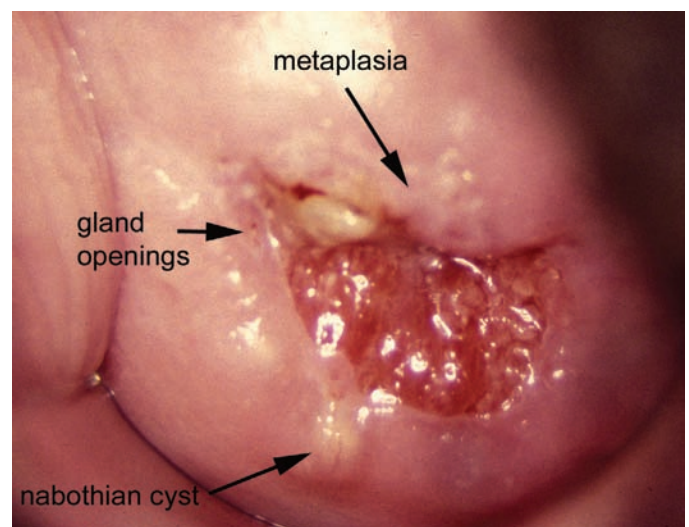

FIGURE 88-4 Normal transformation zone viewed with colposcopy. Note the squamocolumnar junction separating the red columnar epithelium from the pink squamous epithelium. Gland openings, nabothian cysts, and metaplasia are all part of this normal transformation zone. There is a white area of normal metaplasia on the anterior lip and a yellowish nabothian cyst on the posterior lip. (Courtesy of E.J. Mayeaux, Jr., MD.)

- Squamous metaplasia is the physiologic, normal process whereby columnar epithelium transforms into squamous epithelium. At the SCJ, it appears as a “ghostly white” or white-blue film with the application of acetic acid. It is usually sharply demarcated toward the cervical os and has very diffuse borders peripherally (**Figure 88-4**).
- TZ is the geographic area between the original squamous epithelium (before puberty) and the current SCJ. It may contain gland openings, nabothian cysts, and islands of columnar epithelium surrounded by metaplastic squamous epithelium (**Figures 88-3** and **88-4**).
- In some women, the juvenile type TZ persists into adulthood or is present after trauma or childbirth and is termed an ectropion (**Figure 88-8**). It has a reddish appearance similar to granulation tissue. Ectropion is common in adolescents, pregnant women, and those taking estrogen-containing contraceptives. Although usually asymptomatic, vaginal discharge and postcoital bleeding may occur.⁶
- Other nondysplastic colposcopic findings:
 - Nabothian cysts are normal areas of mucus-producing epithelium that are “roofed over” with squamous epithelium (**Figure 88-4**). They may appear translucent or opaque, whitish to yellow, and can range from a few millimeters to several centimeters in size. They always occur in the cervical TZ. They are usually asymptomatic and do not require any treatment.²
 - Cervicitis from an infection may make colposcopic assessment for dysplasia and cervical cancer difficult. Cervicitis appears as friable, inflamed epithelium, often in the presence of a vaginal discharge. *Trichomonas* may cause an inflamed cervix that has a strawberry appearance (**Figure 88-5** and Chapter 84, *Trichomonas* Vaginitis).
 - Atrophic vaginal or cervical epithelium is frequently white and easily traumatized (**Figure 88-6** and Chapter 81, Atrophic Vaginitis).
 - Cervical polyps are focal benign hyperplastic protrusions of the endocervical folds. They usually appear as polypoid growths protruding for the cervical os.³

BIOPSY

- The colposcope is used to examine the cervix for signs of dysplasia or cancer before performing cervical biopsies (see Chapters 89, Colposcopy of Low-Grade Lesions, 90, Colposcopy of High-Grade Lesions, and 91, Colposcopy of Cervical Cancer for details of suspicious colposcopic findings).

DIFFERENTIAL DIAGNOSIS

- Friability from infections must be differentiated from dysplastic changes by a history of possible exposure to STDs, presence of discharge, wet prep, and STD testing.

MANAGEMENT

NONPHARMACOLOGIC

- Nabothian cysts do not require any treatment. If you tell patients that they have a nabothian cyst, please tell them that this is a normal finding.

FIGURE 88-5 Colposcopic view of *Trichomonas* infection. Note disruption of the epithelium with petechiae and pinpoint bleeding producing the “strawberry” cervix. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 88-6 Colposcopic view of cervical atrophy and a benign endocervical polyp in a postmenopausal woman. Note the pale epithelium and the polyp extending from the cervical os. (Courtesy of E.J. Mayeaux, Jr., MD.)

MEDICATIONS

- Atrophic vaginal or cervical epithelium can be treated with intravaginal estrogen for 2 to 4 weeks before colposcopy in order to “normalize” the epithelium. **SOR C** This is generally safe, even if dysplasia or cancer is present, because the duration of therapy is short, and these lesions do not express any more estrogen receptors than a normal cervix.⁷
- Vaginitis is treated with antiinfectives once the source is diagnosed.
- Treatment for cervical polyps is removal by twisting the polyp with ringed forceps. Smaller polyps may be removed with colposcopy biopsy forceps. Polyps with a thick stalk may require surgical or electrosurgical removal. If polyps are removed after a recently abnormal Pap test, the polyp should be sent for analysis as dysplasia may be found on the polyp.⁸
- Cervical dysplastic changes should be handled according to national evidence-based guidelines (see Chapters 89, Colposcopy of Low-Grade Lesions and 90, Colposcopy of High-Grade Lesions).⁹
- An ectropion may be treated with ablation (such as cervical cryotherapy) if significant discharge or postcoital bleeding is present after dysplasia and cancer have been ruled out.²

FOLLOW-UP

- If an infection coexists with an abnormal Pap smear or grossly abnormal appearing cervix, the infection should be treated and the colposcopic assessment should be performed 1 month later.

PATIENT EDUCATION

- Patients should be discouraged from douching as it irritates the mucous membranes, disrupts normal flora, and makes acquisition of an STD more likely if exposed. Safer-sex education should be given to all patients at risk of acquiring an STD.

89 COLPOSCOPY OF LOW-GRADE LESIONS

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 23-year-old woman has a low-grade squamous intraepithelial lesion on her Papanicolaou (Pap) test. One colposcopic view of her cervix shows acetowhite changes consistent with a cervical intraepithelial neoplasia grade 1 lesion (CIN 1) (**Figure 89-1**). She has no other suspicious findings and biopsy of the acetowhite area confirms CIN 1. The endocervical curettage is negative for disease. During the follow-up visit, the doctor and patient together decide to proceed with watchful waiting and repeat Pap tests at 6 and 12 months.

INTRODUCTION

Our knowledge of the genesis and development of cervical cancer has grown greatly over the last 20 years. It was once believed that human papillomavirus (HPV) infection and CIN 1 disease were the first steps in cancer formation. We now know that HPV infection and CIN 1 are essentially the same thing and will resolve without treatment in most immunocompetent women.

EPIDEMIOLOGY

- In low-grade squamous intraepithelial lesion (LGSIL) tests, the abnormalities are typically associated with HPV infection or CIN grade 1 lesions.¹ Overall rates of Pap test abnormalities are often estimated from regional studies. For example, in an observational cohort study of routine cervical tests in the Northwest United States, in women of all ages (n = 150,052), atypical squamous cells was diagnosed at a rate of 9.8 per 1000, LGSIL was diagnosed at a rate of 3.5 per 1000, and negative routine tests occurred at a rate of 278.5 per 1000.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Essentially all CIN is caused by HPV. Ten percent to 15% of CIN 1 lesions progress to CIN 2-3I, and 0.3% progress to cervical cancer.³
- There is no way to determine which CIN 1 lesions (**Figures 89-1** to **89-3**) or simple HPV lesions (**Figures 89-4** and **89-5**) will regress or progress.
- Colposcopy is the standard of care for assessing abnormal Pap tests and cervical dysplasia. It entails the use of a field microscope to examine the cervix after acetic acid (**Figures 89-1** to **89-4**) and Lugol iodine (**Figure 89-5**.) Ten percent to 15% of CIN 1 lesions progress to CIN 2 or 3, and 0.3% progress to cervical cancer.³
- An atypical transformation zone is defined as a transformation zone with findings suggesting cervical dysplasia or neoplasia. Differences in thickness, density of the cells, degree of differentiation, and

FIGURE 89-1 Colposcopic view of acetowhite changes on the cervix of cervical intraepithelial neoplasia grade 1 lesions after the application of acetic acid. Note the irregular geographic borders. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 89-2 Another colposcopy view of acetowhite changes on the cervix of cervical intraepithelial neoplasia grade 1 lesions. (Courtesy of E.J. Mayeaux, Jr., MD.)

keratin production determine the color and opacity of the epithelium, and may produce the abnormal findings of leukoplakia and acetowhite epithelium.

RISK FACTORS

- Sexual intercourse.
- Other types of sexual activity including digital/anal, oral/anal, and digital/vaginal contact.
- Immunosuppression.

DIAGNOSIS

CLINICAL FEATURES

- The diagnosis of low-grade cervical abnormalities is made on colposcopic examination. Findings consistent with this diagnosis include:¹
 - Acetowhite changes (**Figures 89-1 to 89-4**). A transient, white-appearing epithelium following the application of acetic acid may be abnormal and correlates with higher nuclear density. The more sharp and angular the margin is, the likelier it is to be dysplastic. The margins of low-grade disease are usually feathery or geographic borders. Most low-grade lesions are snowy white with a shiny surface. A uniformly papillary surface is often indicative of HPV disease.
 - Punctuation is a stippled appearance of small looped capillaries seen end-on, often found within acetowhite area, appearing as fine-to-coarse red dots. Fine punctuation has fine-caliber vessels that are regularly spaced, and is usually associated with benign conditions or low-grade disease (**Figures 86-3 and 86-4**).
 - Lack of iodine staining (Schiller test) may be used when further clarification of potential biopsy sites is necessary (**Figure 89-5**). It need not be used in all cases. The sharp outlining afforded by Lugol solution can be dramatic and very helpful.

LABORATORY TESTING⁴

- High-risk HPV testing can be used to further define a patient's risk for dysplasia and cancer after an atypical squamous cell (ASC) Pap result. Patients with ASC and a positive high-risk HPV test should be triaged to immediate colposcopy and patients with a negative HPV test may be triaged to re-Pap in 1 year.
- High-risk HPV testing may also be used in conjunction with cytology testing to screen low-risk women at 3-year intervals.

BIOPSY

- Biopsy is usually indicated to establish the histologic grade of the abnormalities present.

DIFFERENTIAL DIAGNOSIS

- CIN 1 and HPV lesions must be differentiated from nonmalignant inflammatory lesions such as yeast vaginitis and sexually transmitted diseases, which usually present with vaginal itching, odor, and/or discharge (see Chapter 83, *Candida* Vulvovaginitis).

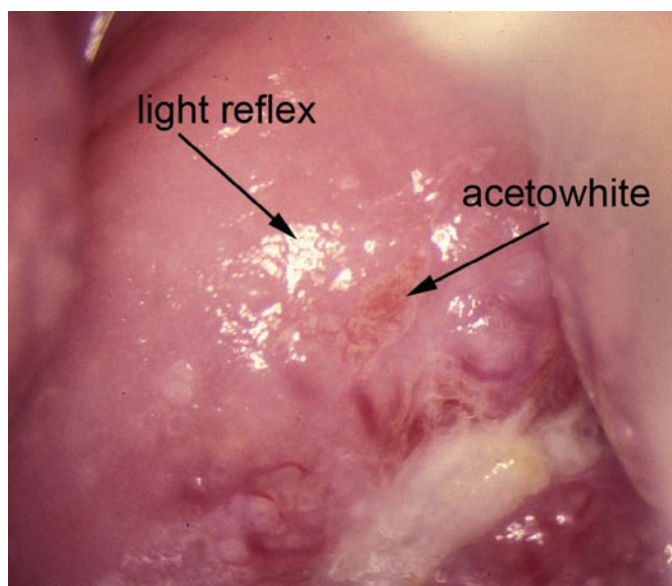

FIGURE 89-3 Colposcopy view of an indistinct acetowhite lesion on the anterior lip. Note the light reflex just above the lesion that may be confused with an actual lesion. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 89-4 Colposcopy view of condyloma of the cervix. Note the bright acetowhite effect that is common on condyloma. (Courtesy of E.J. Mayeaux, Jr., MD.)

- High-grade dysplasia (CIN 2 and CIN 3) and cancer must also be ruled out, usually by colposcopic examination and biopsy (see Chapter 90, Colposcopy of High-Grade Lesions).

MANAGEMENT

NONPHARMACOLOGIC

- According to the 2006 consensus guideline, the preferred treatment for women with CIN 1 and satisfactory colposcopy is repeat cytology at 6 and 12 months or DNA testing for HPV types at 12 months.^{3,5} **SOR B** Most cases of CIN 1 spontaneously regress.
- Observation without treatment is acceptable in pregnant women with CIN 1 and in women with unsatisfactory colposcopy.^{3,5} **SOR B**
- Pap test screening is not recommended for females younger than the age of 21 years, but if they are inappropriately screened, observation without treatment is recommended for CIN 1 disease.

COMPLEMENTARY AND ALTERNATIVE THERAPY

- In one study, oral supplements of indole-3-carbinol were shown to promote regression in high-grade cervical dysplasias when administered orally for 12 weeks.⁶ **SOR B** Indole-3-carbinol occurs naturally in cruciferous vegetables, such as broccoli, cabbage, cauliflower, Brussels sprouts, collard greens, and kale, or can be purchased as a supplement.

SURGICAL

- Treatment options for CIN can be grouped into chemically destructive, surgical ablative, and surgical excisional methods. Cryotherapy, laser, and loop electrosurgical methods are commonly employed when treatment is selected.
- Candidates for outpatient cervical cryotherapy are patients with smaller lesions that do not enter the cervical os. Endocervical sampling is recommended before applying any ablative treatment.^{3,5} **SOR B**
- Large lesions (more than 1 inch in diameter, more than a 0.5 inch from the os, or involving more than 2 cervical quadrants) may be more appropriate for loop or laser therapy.^{3,5} **SOR B**

PREVENTION

- The patient should also be counseled that an HPV vaccine may still be of benefit, if indicated. The U.S. Advisory Committee on Immunization Practices (ACIP) recommends giving the vaccine to girls and women in the indicated age group (11 to 26 years of age) even if they have had an abnormal Pap test; although it will not change the course of the current infection, it will protect from any HPV types to which the patient has not yet been exposed.⁷
- According to the National Cancer Institute, scientific evidence supports the following for prevention of HPV infection.⁸
 - Abstinence from sexual activity.
 - Barrier protection and/or spermicidal gel during sexual intercourse.
 - Vaccination against HPV-16/HPV-18.

FIGURE 89-5 Colposcopic view of a cervix after Lugol solution is applied. The abnormal cervical intraepithelial neoplasia grade 1 lesion is the area on the cervix that does not stain brown with the iodine in the Lugol solution. The areas that do not stain can then be biopsied. This is called the Schiller test. (Courtesy of E.J. Mayeaux, Jr., MD.)

FOLLOW-UP

- Follow-up is in 4- to 6-month intervals until the patient has two serial normal examinations, with colposcopy or colposcopy interspersed with Pap tests. Recurrence is most common in the first 2 years after therapy. Recurrences are most common in the os and on the outside margins.
- After two consecutive negative Pap tests or one negative high-risk HPV DNA test, patients should continue to be routinely screened.

PATIENT EDUCATION

- Smoking cessation counseling is an important part of therapy for women who continue to smoke (see Chapter 236, Tobacco Addiction).

90 COLPOSCOPY OF HIGH-GRADE LESIONS

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 36-year-old woman presented for follow-up of a persistently abnormal Papanicolaou (Pap) test. She is a smoker and has had multiple new sexual partners in the last few years. Although she has had several “abnormal Pap tests” in the past, she states she has never needed treatment. She was found to have a dense acetowhite (AW) lesion on colposcopy that was biopsied (**Figure 90-1**). The pathology returned cervical intraepithelial neoplasia grade 3 (CIN 3) and the patient was treated with loop electrosurgery. She had negative margins on the loop electrosurgical excision procedure specimen and remained recurrence-free at 3 years.

INTRODUCTION

High-grade squamous intraepithelial lesions in adult women are considered true cancer precursors because if left untreated, they have a significant chance of developing into invasive cancer.

SYNONYMS

Cervical intraepithelial neoplasia (CIN 3 and CIN 2) are high-grade lesions.

EPIDEMIOLOGY

- Overall rates of Pap test abnormalities are usually estimated from local or regional studies. For example, in an observational cohort study of routine cervical tests in the Northwest United States, in women of all ages ($n = 150,052$), high-grade squamous intraepithelial lesion was diagnosed at a rate of 0.8 per 1000 compared to negative routine tests that were diagnosed at a rate of 278.5 per 1000.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- In high-grade squamous intraepithelial lesions, the abnormalities are immature parabasilar cell types. They have an increased nuclear-to-cytoplasmic ratio, enlarged hyperchromatic nucleoli, few nucleoli, and a reticular or granular appearance.
- On histology, abnormal maturation and nuclear atypia defines CIN. Koilocytosis (perinuclear cytoplasmic vacuolization) is indicative of human papillomavirus (HPV) infection and may be found with high-grade CIN. High-grade CIN is diagnosed when immature basaloid cells with nuclear atypia occupy greater than the lower one third of the epithelium. With increasing lesion severity, there is also increased nuclear crowding, pleomorphism, normal and abnormal mitosis, and loss of polarity.²

FIGURE 90-1 Dense acetowhite (white after application of vinegar) lesions with “rolled” edges in a patient with high-grade disease. Her colposcopically directed biopsies showed cervical intraepithelial neoplasia grade 3. (Courtesy of E.J. Mayeaux, Jr., MD.)

- Traditionally, high-grade CIN is thought to arise as a small focus within a larger area of low-grade CIN that expands and eventually replaces much of the low-grade lesion.
- This “monoclonal” theory is supported by the fact that there is a 5-year difference between the peak prevalence of CIN 1 and CIN 2 or 3, and detection of a low-grade squamous intraepithelial lesion. Pap greatly increases the risk that a high-grade CIN will be found on subsequent tests.
- It has been difficult to document the rate of progression because most studies use cervical biopsy to establish an accurate diagnosis, which influences the rate of disease progression.
- With the discovery that most CIN 1 lesions regress or persist, the question has been raised as to whether high-grade CIN might be a process that develops concurrently and somewhat independently from low-grade CIN.
- This theory is supported by the fact that CIN 3 can develop without a detectable preceding low-grade CIN lesion, and high-grade CIN is almost always found closer to the squamocolumnar junction than concomitant low-grade lesions. It has also been found that women who turned HPV-16/-18–positive had a 39% rate of high-grade CIN at 2 years compared to HPV-negative women.
- Schiffman et al. reported that both CIN 1 and CIN 2 or 3 lesions developed within the same time frame in a large group of women who turned HPV-positive and were followed for 4 years.³
- Which theory is most correct is a matter of debate. Many practitioners still treat CIN 1 level lesions on the basis of the monoclonal theory or on the theory that if both lesions arise concomitantly, then treating CIN 1 lesions may be the best way of eliminating high-grade CIN. Others promote the idea of observing CIN 1 lesions and treating only high-grade CIN lesions.

RISK FACTORS⁴

- HPV infection.
- Nonuse of barrier protection and/or spermicidal gel during sexual intercourse.
- No Pap testing within the last 3 years in low-risk women with a cervix or within 1 year for high-risk women.
- Nonvaccination status for HPV-16 and HPV-18.
- Tobacco smoking.

DIAGNOSIS

CLINICAL FEATURES

- Leukoplakia, as shown in **Figure 90-2**, is typically an elevated, white plaque seen prior to the application of acetic acid. It is caused by a thick keratin layer that obscures the underlying epithelium and may signal severe dysplasia or cancer. Although it may be associated with benign findings, it always warrants a biopsy.
- AW epithelium following the application of acetic acid is typical for CIN 2 and 3 lesions (**Figure 90-1**). The AW effect tends to develop more slowly than in lower-grade lesions and to persist

FIGURE 90-2 Leukoplakia (white lesion before application of vinegar) of the cervix seen with colposcopy in a patient with high-grade squamous intraepithelial lesion. (Courtesy of E.J. Mayeaux, Jr., MD.)

longer. The margins of high-grade CIN are straighter and sharper compared to the vague, feathery, geographic borders of CIN 1 or HPV disease.

- With increasing levels of CIN, desmosomes (intracellular bridges) that attach the epithelium to the basement membrane are often lost, producing an edge that easily peels. This loss of tissue integrity should raise the suspicion of high-grade dysplasia. The extreme expression of this effect is the ulceration that sometimes forms with invasive disease.
- High-grade CIN lesions are usually proximal to or touch the squamocolumnar junction, even when contained in larger lesions (Figures 90-1 to 90-5).
- Nodular elevations on the surface of lesions and ulceration are suspicious for high-grade or invasive cancer.
- Increases in local factors such as tumor angiogenesis factor or vascular endothelial growth factor, which are much more commonly produced by CIN 3 lesions, cause growth of abnormal surface vasculature, producing punctuation (Figures 90-3 and 90-4), mosaicism (Figures 90-5 and 90-6), and frankly abnormal vessels. However, most high-grade lesions do not develop any abnormal vessels.
- Punctuation is a stippled appearance of small looped capillaries seen end-on, often found within AW area, appearing as fine-to-coarse red dots (Figures 90-3 and 90-4). Course punctuation represents increased caliber vessels that are spaced at irregular intervals, and is more highly associated with increasing levels of dysplasia.
- Mosaicism is an abnormal pattern of small blood vessels suggesting a confluence of “tiles” or a “chicken-wire pattern” with reddish borders. Mosaicism represents capillaries that grow on or near the surface of the lesion that forms partitions between blocks of proliferating epithelium (Figures 90-5 and 90-6). It develops in a manner very similar to punctuation and is often found in the same lesions. Course mosaic forms a consistently irregular cobblestone effect with dilated coarse vessels which is highly associated with CIN 2 and 3.

TYPICAL DISTRIBUTION

- CIN 2 or 3 disease usually touches the active squamocolumnar junction (SCJ).
- When CIN 2 or 3 coexists in the same lesion with a lower-grade lesion, the higher-grade lesion often presents with a sharply defined internal border (also known as a border-within-a-border). The higher-grade disease is usually proximal to the os.

LABORATORY TESTING

- High-risk HPV testing is not useful for the diagnosis of CIN 2 or 3. It can be useful for posttreatment follow-up.⁵

BIOPSY

- Biopsy is usually indicated to establish the histologic grade of the abnormalities present. Biopsies are performed under colposcopic direction.

DIFFERENTIAL DIAGNOSIS

- CIN 2 and 3 lesions must be differentiated from nonmalignant inflammatory lesions, especially trichomoniasis and *Chlamydia*

FIGURE 90-3 Course punctuation of the cervix seen through the colposcope in a patient with high-grade disease. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 90-4 Acetowhite epithelium and course punctuation on the same cervix (arrow). The biopsies of this area showed cervical intraepithelial neoplasia grade 3. (Courtesy of E.J. Mayeaux, Jr., MD.)

infections, which usually present with vaginal itching, odor, and/or discharge (see Chapter 84, *Trichomonas* Vaginitis, and Chapter 85, *Chlamydia* Cervicitis).

- Flat HPV lesions may mimic the dense AW lesions of CIN 2 and 3.
- CIN 2 and 3 lesions must be differentiated from both CIN 1 and cancer (see Chapter 89, Colposcopy of Low-Grade Lesions, and Chapter 91, Colposcopy of Cervical Cancer).

MANAGEMENT

- Except in special circumstances, women with biopsy-confirmed CIN 2 or 3 should be treated. CIN 2 may be followed with colposcopy and Pap tests in patients who have not attained their 21st birthday.^{5,6}
- Effective treatment of CIN 2 and 3 requires the removal of the entire transformation zone rather than just the removal of the lesion. When colposcopy is satisfactory, any ablative or excisional modality will treat CIN effectively.⁵ **SOR A** However, because excisional modalities allow for the pathologic identification of unanticipated microinvasive or occult invasive cancer, some physicians prefer these methods to treat biopsy-confirmed CIN 2 and 3.² **SOR C**
- Both excision and ablation are acceptable treatment choices for non-pregnant adult women with a histologic diagnosis of CIN 2 and 3 and satisfactory colposcopy. For adolescents and young women with a histologic diagnosis of CIN 2, observation with colposcopy and cytology at 6-month intervals is preferred, but treatment is acceptable.
- Observation is unacceptable in women with CIN 2 except during pregnancy and in very compliant adolescents with satisfactory colposcopy and negative results on endocervical curettage.⁶ **SOR C**
- A randomized clinical trial demonstrated that condom use promotes regression of CIN and clearance of HPV.⁷ **SOR B**
- Because a small number of women with biopsy-confirmed CIN 2 or 3 and unsatisfactory colposcopy have occult invasive cancer, excisional procedures should be performed. Cold knife and loop electrosurgical excision procedure conizations effectively diagnose and treat these women.⁶ **SOR B**

COMPLEMENTARY AND ALTERNATIVE THERAPY

- In one study, oral supplements of indole-3-carbinol have been shown to promote regression in high-grade cervical dysplasias when administered orally for 12 weeks.⁸ **SOR B** Indole-3-carbinol occurs naturally in cruciferous vegetables, such as broccoli, cabbage, cauliflower, Brussels sprouts, collard greens, and kale, or can be purchased as a supplement.

PREVENTION

- The patient should also be counseled that an HPV vaccine may still be of benefit if indicated. The U.S. Advisory Committee on Immunization Practices (ACIP) recommends giving the vaccine to women in the indicated age group (11 to 26 years of age) even if they have had an abnormal Pap test. Although it will not change the course of the current infection, it will protect her from other HPV types to which she has not yet been exposed.⁶

FIGURE 90-5 Colposcopy with findings of mosaicism in a patient with cervical intraepithelial neoplasia grade 3. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 90-6 High-power colposcopy image of a patient with cervical intraepithelial neoplasia grade 3. Note the course pattern consisting of large caliber vessels, irregular tile shapes, and irregular sizes. There are also a few punctations contained within the mosaic pattern, which is common. (Courtesy of E.J. Mayeaux, Jr., MD.)

- According to the National Cancer Institute (NCI), scientific evidence supports the following for prevention of cervical cancer:⁹
 - Prevention of HPV infection through abstinence from sexual activity and barrier protection and/or spermicidal gel during sexual intercourse.
 - Vaccination against HPV-16/HPV-18.
 - Screening via gynecologic examinations and cytologic screening.
- Avoidance of all tobacco smoke.

PROGNOSIS

- For untreated CIN 2, approximately 43% will spontaneously regress, 35% will persist, and 22% will progress to carcinoma in situ or invasive cancer.² The regression rate of CIN 2 is higher in adolescents.
- For untreated CIN 3, approximately 32% will regress, 56% will persist, and 14% of CIN 3 will progress to carcinoma in situ or invasive cancer.²

FOLLOW-UP

- After treatment for CIN 2 or 3, acceptable management methods include cytology with or without colposcopy at 4- to 6-month intervals until three negative evaluations have been obtained, or HPV DNA testing no sooner than 6 months after treatment.^{5,6} **SOR C**
- The preferred management for CIN identified at the margin of a diagnostic excisional procedure or in postprocedure endocervical sampling is colposcopy and endocervical sampling at the 4- to 6-month follow-up evaluation.^{5,6} **SOR C**

PATIENT EDUCATION

- Tobacco smoking has been linked to the development and recurrence of CIN. Part of any treatment program should include smoking cessation.

91 COLPOSCOPY OF CERVICAL CANCER

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 51-year-old woman presents with postcoital bleeding. She has not had a period in 3 years, but has started spotting after intercourse. Her last Papanicolaou (Pap) smear was after the birth of her last child 25 years ago and was normal. Other than an occasional mild hot flash, she has no other complaints. On colposcopy she was found to have a densely acetowhite lesion with abnormal vessel near the cervical os (**Figure 91-1**). Biopsy demonstrated invasive squamous cell carcinoma. The patient then had a radical hysterectomy with pelvic/paraortic lymphadenectomy. Fortunately her lymph nodes were all negative.

INTRODUCTION

Colposcopy is an important visualization technique used to investigate abnormal Pap smears and to direct biopsies for histologic diagnosis of cervical cancer. Because human papillomavirus (HPV) is present in 95% to 100% of all squamous cell cancers (SCCs), the International Agency for Research on Cancer proclaimed cervical cancer to be the first human cancer known to have a single necessary cause.^{1,2}

EPIDEMIOLOGY

- Carcinoma of the cervix is the second most common cancer in women worldwide with an estimated 400,000 to 500,000 cases of cervical cancer diagnosed each year.^{3,4}
- In the United States, an estimated 12,170 new cases and approximately 4220 deaths occur annually, even though more than 50 million Pap smears are performed each year.⁵
- Half of the cases occur in women never screened and an additional 10% in women not screened within the past 5 years.⁶
- Ninety-three percent of invasive cervical cancers are SCCs (**Figures 91-1 to 91-4**). They almost all contain HPV DNA, and 90% are subtypes 16 or 18, which are most virulent.⁷
- Approximately 7% of cases are adenocarcinomas but these are on the rise⁷ (**Figure 91-5**).
- It is rare to find invasive cancer of the uterine cervix in pregnancy. The incidence varies from 1 to 15 cases per 10,000 pregnancies, and the prognosis is similar to that of nonpregnant patients.⁸
- The peak prevalence of invasive cervical cancer is 40 to 50 years of age.⁹

FIGURE 91-1 Colposcopic view of invasive squamous cell carcinoma. The lesion is densely acetowhite with abnormal vessels on the anterior lip just above the cervical os. (Courtesy of E.J. Mayeaux, Jr., MD.)

FIGURE 91-2 Colposcopic view of invasive squamous cell cancer with abnormal vessels. (Courtesy of E.J. Mayeaux, Jr., MD.)

ETIOLOGY AND PATHOPHYSIOLOGY

- Oncogenic HPV serve as initiators, and other factors relating to immune status, such as cigarette smoking, nutrition, or other genital infections, may be promoters.¹⁰
- Cervical cancer is unique in that no other human cancer has been shown to have such a clearly identified cause, which are oncogenic strains of HPV.¹

RISK FACTORS¹¹

- HPV infection.
- Nonuse of barrier protection and/or spermicidal gel during sexual intercourse.
- No Pap testing within the last 3 years in low-risk women with a cervix or within 1 year for high-risk women.
- Nonvaccination status for HPV-16 and HPV-18.
- Tobacco smoking.

DIAGNOSIS

CLINICAL FEATURES

- Leukoplakia is typically an elevated, white plaque seen prior to the application of acetic acid. It is caused by a thick keratin layer that obscures the underlying epithelium (**Figure 91-1**). It always warrants a biopsy.
- Early invasion often is associated with a decline in the acetowhite reaction. Yellow hued color change is also a marker for early or frank invasive lesions (**Figure 91-4**).
- With increasing levels of cervical intraepithelial neoplasia (CIN), desmosomes (intracellular bridges) that attach the epithelium to the basement membrane are often lost, producing an edge that easily peels. This loss of tissue integrity should raise the suspicion of high-grade dysplasia. The extreme expression of this effect is the ulceration that sometimes forms with invasive disease. The ulcer can have a rolled edge around the ulcer without vessels visible in the ulcer cavity.
- Nodular elevations and ulceration are suspicious for high-grade or invasive cancer.
- Course punctuation and course mosaic patterns may be associated with high-grade dysplasia or cancer (see Chapter 90, Colposcopy of High-Grade Lesions).
- Abnormal blood vessels are atypical irregular surface vessels that have lost their normal arborization or branching pattern (**Figures 91-1** and **91-2**). This represents an exaggeration of the abnormalities of punctuation and mosaicism, and it usually represents increasing severity of the lesion. They can be indicative of invasive cancer, but can occasionally be seen with high-grade CIN. These vessels are often best seen before application of acetic acid. They are usually nonbranching, appear with abrupt courses and patterns, and often appear as commas, corkscrews,

FIGURE 91-3 Colposcopic view of invasive squamous cell cancer. Note how the cancer has replaced the entire surface of the cervix with friable epithelium. (Courtesy of Daron Ferris, MD.)

FIGURE 91-4 Colposcopic view of a rarer yellow-hued invasive squamous cell cancer of the cervix. (Courtesy of E.J. Mayeaux, Jr., MD.)

hairpins, or spaghetti. They may also appear as coarse parallel vessels. There is no definite repetitive pattern as with punctuation or mosaic.

- A thin watery vaginal discharge is the most common early complaint of a woman with cervical cancer. As the lesions progress or enlarge, complaints occur of postcoital bleeding or painless intermenstrual bleeding.
- More advanced lesions present with heavier and frequent bleeding until it may become continuous. Pain, hematuria, obstipation, and rectal bleeding are symptoms of late disease because of local direct invasion of surrounding paracervical structures. Lower-extremity edema may occur with pelvic sidewall involvement of tumor. Hemorrhage and uremia are preterminal events.
- Findings on speculum examination include an exophytic mass (Figures 91-3 and 91-5), cervical ulcer, or barrel-shaped cervix.

LABORATORY TESTING

- Although HPV testing is used for screening for cervical cancer, it is not useful in the diagnosis of the disease.

IMAGING

- The staging of biopsy proven cervical cancer remains clinical. Physical examination with cystoscopy and proctoscopy usually starts the process. Routine x-ray studies are also used, including chest x-ray, intravenous pyelogram, and barium enema.

BIOPSY

- Colposcopy and biopsy are needed to make the diagnosis. A histologic biopsy that is suspicious, but not confirmatory, of invasion requires cervical conization for definitive diagnosis. A biopsy of microinvasive carcinoma requires conization for definitive diagnosis and to rule out a more invasive lesion. A biopsy with definitive invasion greater than 5 mm does not require conization to plan therapy. Any frank lesion of the cervix requires biopsy for diagnosis.

DIFFERENTIAL DIAGNOSIS

- Because some cancers of the cervix ulcerate, cervical cancer must be differentiated from nonmalignant ulcerative diseases such as herpes virus infections (see Chapter 129, Herpes Simplex).
- Cervical cancer must be differentiated from CIN II and CIN III lesions (see Chapter 90, Colposcopy of High-Grade Lesions).
- Flat HPV lesions may mimic dense acetowhite lesions or leukoplakia (see Chapter 133, Genital Warts). A colposcopically directed biopsy can distinguish between these conditions.

MANAGEMENT

- **Table 91-1** shows the staging and treatment methods for cervical cancer.

FIGURE 91-5 Adenocarcinoma of the cervix. (Courtesy of E.J. Mayeaux, Jr., MD.)

TABLE 91-1 Staging and Treatment of Cervical Cancer*†

Stage	Description	Treatment	5-Year Survival (%)
0	Carcinoma in situ	Surgical excision or ablation	
I	Tumor is confined to the cervix		91.3
IA	Microinvasive disease with the lesion not grossly visible. No deeper than 5 mm and no wider than 7 mm	Simple hysterectomy or careful observation after cone biopsy (with clear margins)	98.1
IB	Larger tumor than in IA or grossly visible, confined to cervix	Radical hysterectomy with pelvic node dissection or external-beam and intracavitary radiotherapy (equally effective)	88.2
II	Extends beyond the cervix, but does not involve the pelvic sidewall or lowest third of the vagina		60.7
IIA	Involvement of the upper two-thirds of vagina, without lateral extension into the parametrium	Radical hysterectomy with pelvic node dissection or pelvic radiotherapy	67.2
IIB	Lateral extension into parametrial tissue	Pelvic radiotherapy	57.9
III	Involves the lowest third of the vagina or pelvic sidewall or causes hydronephrosis		46.8
IIIA	Involvement of the lowest third of the vagina	Pelvic radiotherapy with or without cisplatin-based therapy	38.6
IIIB	Involvement of pelvic sidewall or hydronephrosis or nonfunctioning kidney	Pelvic radiotherapy with or without cisplatin-based therapy	47.7
IV	Extensive local infiltration or has spread to a distant site		
IVA	Spread of the tumor onto adjacent pelvic organs	Pelvic radiotherapy with cisplatin-based therapy	15.5
IVB	Distant metastases	Chemotherapy with or without pelvic radiotherapy	14.6

*Staging system based on the Federation of International Gynecologists and Obstetricians. *Treatment Option Overview*. http://www.cancer.gov/cancertopics/pdq/treatment/cervical/HealthProfessional/page4#Section_61. Accessed February 18, 2012.

†Survival data based on the SEER Survival Monograph: *Cancer Survival Among Adults: US SEER Program, 1988-2001, Patient and Tumor Characteristics. Chapter 14: Cancer of the Cervix Uteri*. http://seer.cancer.gov/publications/survival/surv_cervix_uteri.pdf.

PREVENTION

- Most cases are detected in the precancerous stages or as early disease in industrialized countries through the use of the Pap test and HPV testing.¹² The current death rate, however, is far higher than it should be because the Pap test and HPV testing are not performed on approximately 33% of eligible women.

PROGNOSIS

- The prognosis for patients with cervical cancer is mostly defined by the extent of disease at the time of diagnosis (see **Table 91-1**).¹³

Clinical stage, volume and grade of tumor, histologic type, lymphatic spread, and vascular invasion also affect prognosis. The factors that best predict decreased disease-free survival are depth of stromal invasion, capillary-lymphatic space involvement by tumor, and increased tumor size.

FOLLOW-UP

- Early stage (International Federation of Gynecology and Obstetrics stages IA to IIA) SCC is treated with radical hysterectomy and pelvic/paraortic lymphadenectomy or radiation therapy. In patients with positive resection margins or positive lymph nodes, postoperative chemotherapy and/or radiotherapy is often used.

- Stages IB2 and IIA disease is treated with either chemoradiotherapy alone, surgery followed by chemoradiotherapy, or chemotherapy and radiotherapy followed by hysterectomy.
- For patients with stages IIB, III, and IVA cervical SCC, chemotherapy plus radiotherapy is usually recommended over radiation therapy alone.

PATIENT EDUCATION

- Fertility-sparing surgery is available for very early stage cervical cancer. Menopausal symptoms are a common side-effect of chemotherapy.

SECTION 5 BREAST

92 BREAST ABSCESS
AND MASTITIS

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 23-year-old woman, who is currently breastfeeding and 6 weeks postpartum, presents with a hard, red, tender, indurated area medial to her right nipple (**Figure 92-1**). She also has a low-grade fever. Because there is a local area of fluctuance, incision and drainage is recommended. The area is anesthetized with 1% lidocaine and epinephrine and drained with a #11 scalpel. A lot of purulence is expressed and the wound is packed. The patient is started on cephalexin 500 mg qid for 10 days to treat the surrounding cellulitis and seen in follow-up the next day. The patient was already feeling better the next day and went on to full resolution in the following weeks.

INTRODUCTION

Mastitis, defined as an infection of the breast, and breast abscesses are typically found in breastfeeding women (**Figure 92-1**). A breast abscess and mastitis unrelated to pregnancy and breastfeeding can occur in older women (**Figure 92-2**).

EPIDEMIOLOGY

- The prevalence of mastitis is estimated to be 2% to 3% of lactating women.¹
- Breast abscess is an uncommon problem in breastfeeding women, with an incidence of approximately 0.1%.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Mastitis is most commonly caused by *Staphylococcus aureus*, *Streptococcus* species, and *Escherichia coli*.
- Recurrent mastitis can result from poor selection or incomplete use of antibiotic therapy, or failure to resolve underlying lactation management problems. Mastitis that repeatedly recurs in the same location, or does not respond to appropriate therapy, may indicate the presence of breast cancer.³

RISK FACTORS

- Risk factors for mastitis include a history of mastitis with a previous child, cracks and nipple sores, use of an antifungal nipple cream in the same month, and use of a manual breast pump.⁴

FIGURE 92-1 Localized cellulitis and breast abscess in a breastfeeding mother. Note the Peau d' orange appearance of the edematous breast tissue. (Courtesy of Nicolette Deveneau, MD.)

FIGURE 92-2 Breast abscess and cellulitis in a 40-year-old woman. Pus was already draining at the time of presentation, but a further incision and drainage through the openings yielded another 30 cc of pus. The patient was treated with oral antibiotics and scheduled to get a mammogram when the infection is cleared. (Courtesy of Richard P. Usatine, MD.)

- Risk factors for breast abscess include maternal age older than 30 years, primiparity, gestational age of 41 weeks, and mastitis.^{2,3} Breast abscess develops in 5% to 11% of women with mastitis, often caused by inadequate therapy.³

DIAGNOSIS

CLINICAL FEATURES

- Mastitis causes a hard, red, tender, swollen area on the breast (**Figures 92-1 to 92-3**). Erythema is less visible in darker skin but the swelling is still prominent (**Figure 92-3**).
- Usually unilateral, so the breast size difference can be obvious (**Figure 92-3**).
- Fever is common.
- Pain usually extends beyond the indurated area.
- It is often associated with other systemic complaints, including myalgia, chills, malaise, and flu-like symptoms.
- Breast abscess can occur with mastitis, except a fluctuant mass is palpable. (In **Figure 92-2**, the fluctuant mass is close to the mid-line with two openings of spontaneous drainage. The remainder of the erythema is the mastitis.)

TYPICAL DISTRIBUTION

- The typical distribution is usually unilateral.

LABORATORY TESTING

- In persistent cases, a mid-stream milk sample may be cultured and antibiotics prescribed based upon the identification and sensitivity of the specific pathogen.

IMAGING

- Ultrasonography may be used to distinguish abscesses from other types of lesions. Abscesses appear as ill-defined masses and have central hypoechoic areas with either septations or low-level internal echoes, and posterior enhancement.⁵

BIOPSY

- Biopsy is needed if a palpable mass remains after the infection is cleared.

DIFFERENTIAL DIAGNOSIS

- Mastitis should be distinguished from plugged lacrimal ducts, which present as hard, locally tender, red areas without associated regional pain or fever.
- Tinea corporis can cause erythema and scaling on any part of the body, including breast. It is often annular and pruritic (see Chapter 138, Tinea Corporis).
- Paget disease of the breast is an intraepithelial neoplasia that may appear as an erythematous patch on the nipple or breast (see Chapter 94, Paget Disease of the Breast).

FIGURE 92-3 Mastitis in a postpartum breastfeeding woman. The right breast was warm, tender, enlarged, and painful. Erythema is barely visible on the areola because of the naturally darker pigmentation of the skin. (Courtesy of Richard P. Usatine, MD.)

MANAGEMENT

NONPHARMACOLOGIC

- Management of mastitis includes supportive measures, such as analgesics, warm compresses, and continued breastfeeding. **SOR C** If the infant cannot relieve breast fullness during nursing, breast massage during nursing or pumping afterwards may help reduce discomfort.
- Frequent breast emptying helps both infectious and noninfectious mastitis. **SOR A** Breastfeeding may continue on both breasts if the incision isn't too painful and it does not interfere with the baby latching on. Otherwise a breast pump may be used on the affected breast for 3 to 4 days until nursing can resume.

MEDICATIONS

- Acetaminophen or an antiinflammatory agent such as ibuprofen may be used for pain control.
- Antibiotic treatment should be initiated with dicloxacillin or cephalexin (500 mg PO 4 times daily) for 10 to 14 days. **SOR A** Consider clindamycin if the patient is allergic to penicillin and/or cephalosporins. **SOR A** Clindamycin 600 mg PO q6h may be a good choice if methicillin-resistant *S. aureus* (MRSA) is suspected. All of the antibiotics recommended are safe for the baby during pregnancy and lactation. Trimethoprim-sulfamethoxazole 1 DS tablet bid is an alternative for MRSA and/or penicillin-allergic patients, but it should be avoided near term pregnancy and in the first 2 months of breastfeeding because of a risk to the baby of kernicterus. Shorter courses of antibiotic therapy may be associated with higher relapse rates. **SOR C**
- For mastitis not associated with breastfeeding, use clindamycin 300 mg PO q6h, or amoxicillin/clavulanate 500 mg PO tid. **SOR C**

COMPLEMENTARY AND ALTERNATIVE THERAPY

- Preliminary data suggests that administration of lactobacilli strains that are naturally occurring in breast milk may be of therapeutic benefit for the management of mastitis during lactation. **SOR C**

SURGICAL

- The management of a breast abscess consists of drainage of the abscess. **SOR A** Antibiotic therapy should be considered and is especially important if there is surrounding cellulitis (see **Figures 92-2 and 92-4**).
- Drainage can usually be performed on abscesses smaller than 3 cm by needle aspiration, with the addition of ultrasound guidance if needed. Abscesses larger than 3 cm treated with needle aspiration have a high recurrence rate. ¹⁰
- If needle aspiration is not effective, incision and drainage should be performed. Incision and drainage is often preferred because it allows for continued drainage through the opening. In many cases a cotton wick is placed to keep the abscess open while the purulence drains over the following days.

REFERRAL OR HOSPITALIZATION

- Hospitalization and intravenous antibiotics are rarely needed but should be considered if the patient is systemically ill and not able to tolerate oral antibiotics.

FIGURE 92-4 Healing after drainage of an abscess and antibiotics for cellulitis. (Courtesy of E.J. Mayeaux, Jr., MD.)

FOLLOW-UP

- If no response is seen within 48 hours or if MRSA is a possibility, antibiotic therapy should be switched to trimethoprim-sulfamethoxazole 1 DS tablet PO bid, or clindamycin 300 mg orally q6h. Avoid trimethoprim-sulfamethoxazole near term pregnancy and in the first 2 months of breastfeeding.

PATIENT EDUCATION

- The patient may take acetaminophen or ibuprofen for pain as these medications are safe while breastfeeding and are indicated for use in children.
- Warm compresses applied before and after feedings can provide some pain relief. A warm bath may also help.
- Instruct the patient to finish the antibiotic prescription, even if the patient feels better in a few days, to lower the risk of bacterial resistance or relapse.
- Continue feedings and, if necessary, use a breast pump to completely empty the breast.
- Educate the parents that the mastitis or the antibiotics will not harm the baby, and that the source of the infection was probably the baby's own mouth.
- Continue to drink plenty of water and eat well-balanced meals.

93 BREAST CANCER

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 55-year-old woman presents for routine screening mammogram. The patient does not have any complaints but has a family history of breast cancer in a sister at age of 40 years. Her mammogram demonstrates an irregular mass with possible local spread (**Figures 93-1 and 93-2**). She is referred to a breast surgeon and the biopsy confirms the diagnosis of breast cancer.

INTRODUCTION

Breast cancer is a major health concern for all women. It is the most common female cancer in the United States, and the second most common cause of cancer death in women after lung cancer.¹

EPIDEMIOLOGY

- In 2007, approximately 178,000 women in the United States were diagnosed with breast cancer.¹ Breast cancer incidence in the United States has doubled over the past 60 years. Since the early 1980s, most of the increase has been in early stage and in situ cancers because of mammogram screening (**Figures 93-1 to 93-4**).
- Approximately 232,620 new cases of invasive breast cancer were expected to be diagnosed in the United States in 2011, and 39,970 were expected to die from the disease.¹
- Globally, breast cancer is the most common cancer, and the leading cause of cancer death in females. Breast cancer incidence rates are highest in North America, Australia-New Zealand, and Europe, and lowest in Asia and sub-Saharan Africa.²
- Locally advanced breast cancer (LABC) has been decreasing in frequency over the past several decades, at least partially as a result of earlier diagnosis because of better screening (**Figures 93-5 to 93-8**). It represents 30% to 50% of newly diagnosed breast cancers in medically underserved populations.³
- Primary inflammatory breast cancer (IBC) is relatively rare, accounting for 0.5% to 2% invasive breast cancers.⁴ However, it accounts for a greater proportion of cases presenting with more advanced disease. IBC is a clinical diagnosis. At presentation, almost all women with primary IBC have lymph node involvement and approximately one third have distant metastases.⁵

ETIOLOGY AND PATHOPHYSIOLOGY

- The incidence of breast cancer increases with age. White women are more likely to develop breast cancer than black women. One percent of breast cancers occur in men.

FIGURE 93-1 A mammogram that demonstrates an irregular mass with possible local spread. (Courtesy of John Braud, MD.)

FIGURE 93-2 A close-up view of the lesion shown in Figure 93-1. (Courtesy of John Braud, MD.)

- Primary risk factors for the development of breast cancer include age older than 50 years, female sex, increased exposure to estrogen (including early menarche and late menopause), and a family history in a first-degree maternal relative (especially if diagnosed premenopausally.).
- Approximately 8% of breast cancers are hereditary and of these one-half are associated with mutations in genes BRCA1 and BRCA2. It is more common in premenopausal women, multiple family generations, and bilateral breasts.⁶ Typically, several family members are affected over at least three generations and can include women from the paternal side of the family.
- A history of a proliferative breast abnormality, such as atypical hyperplasia, may increase a woman's risk for developing breast cancer.
- The selective estrogen receptor modulator tamoxifen (and possibly raloxifene) reduces the risk of developing breast cancer.
- The American Cancer Society, American College of Radiology, American Medical Association, and American College of Obstetrics and Gynecology all recommend starting routine screening at age 40 years.⁷
- The United States Preventive Services Task Force and the 2002 statement by the American Academy of Family Physicians recommend screening mammography every 1 to 2 years for women ages 40 years and older.⁸
- Women who have a family history of BRCA mutation should begin annual mammography between 25 and 35 years of age.⁹ **SOR A**
- MRI screening is more sensitive for detecting breast cancers than mammography and is being used to screen women with BRCA mutations.¹⁰ It is not proven that surveillance regimens that include MRI will reduce mortality from breast cancer in high-risk women.¹⁰
- Although the sensitivity of MRI is higher than that of conventional imaging, MRI has a lower specificity. One study suggests that unnecessary biopsies can be avoided with second-look ultrasound when MRI is positive and mammography is not. Second-look ultrasound can be used to recognize false-positive MRI results and guide biopsies.¹¹

RISK FACTORS

- Positive family history of breast and/or ovarian cancer (especially with BRCA mutations).
- Personal history of breast cancer.
- Increasing age in women.
- Early age at menarche and late menopause.
- Prolonged exposure to and higher concentrations of endogenous or exogenous estrogen.
- Exposure to ionizing radiation.
- Dense breast tissue and atypical hyperplasia.
- Women who have had no children or who had their first child after age 30 have a slightly higher breast cancer risk.
- Low physical activity levels.
- High-fat diet.
- Alcohol intake of two or more drinks daily.

FIGURE 93-3 A screening mammogram of a 55-year-old woman who is without breast complaints. The mammogram demonstrates a significant mass with spiculations. (Courtesy of John Braud, MD.)

FIGURE 93-4 Close-up view of the mass shown in Figure 93-3 demonstrating clear spiculations and microcalcifications. (Courtesy of John Braud, MD.)

DIAGNOSIS

CLINICAL FEATURES

- Detection of a breast mass is the most common presenting breast complaint. However, 90% of all breast masses are caused by benign lesions. Breast pain is also a common presenting problem. Physical examination of the breast should be performed in the upright (sitting) and supine positions. Inspect for differences in size, retraction of the skin or nipple (**Figures 93-5** and **93-6**), prominent venous patterns, and signs of inflammation (**Figures 93-5** and **93-6**). Palpate the breast tissue, axillary area, and supraclavicular areas for masses or adenopathy. Gently squeeze the nipple to check for discharge.
- Most LABCs are both palpable and visible (**Figures 93-7** and **93-8**). Careful palpation of the skin, breasts, and regional lymph nodes is the initial step in diagnosis. The patient in **Figure 93-8** had five palpable lymph nodes at the time of presentation.
- IBC usually presents clinically as a diffuse brawny induration of the skin of the breast with an erythematous edge, and usually without an underlying palpable mass. Patients with de novo IBC typically present with pain and a rapidly enlarging breast. The skin over the breast is warm, and thickened, with a “peau d’orange” (skin of an orange) appearance (**Figures 93-5** and **93-6**). The skin color can range from a pink flushed discoloration to a purplish hue.

TYPICAL DISTRIBUTION

- A mass that is suspicious for breast cancer is usually solitary, discrete, hard, unilateral, and nontender. It may be fixed to the skin or the chest wall.

IMAGING

- More than 90% of breast cancers are identified mammographically.¹² When an abnormality is found, supplemental mammographic views and possibly ultrasound are usually done. Diagnostic mammography is associated with higher sensitivity but lower specificity as compared to screening mammography.¹³

BIOPSY

- Fine-needle aspiration biopsy generally uses a 20- to 23-gauge needle to obtain samples from a solid mass for cytology. Ultrasound or stereotactic guidance is used to assist in collecting a fine-needle aspiration from a nonpalpable lump. Core biopsy uses a 14-gauge or similar needle to remove cores of tissue from a mass. Excisional biopsy is done as the initial procedure or when needle biopsies are negative when the clinical suspicion is high. Guided biopsy and nonguided biopsy are also commonly used to make a definitive diagnosis.

DIFFERENTIAL DIAGNOSIS

- Fibroadenoma usually present as smooth, rounded, rubbery masses in women in their 20s and 30s. A clinically suspicious mass should be biopsied even if mammography findings are normal.
- Benign cysts are rubbery and hollow feeling in women in their 30s and 40s. A cyst can be diagnosed by ultrasound imaging. A simple

FIGURE 93-5 Woman with advanced breast cancer and peau d’orange sign. The skin looks like the skin of an orange as a consequence of lymphedema. (Courtesy of Richard P. Usatine, MD.)

FIGURE 93-6 The patient in **Figure 93-5** showing breast retraction and brawny edema of the breast and arm. (Courtesy of Richard P. Usatine, MD.)

cyst can be aspirated, but a residual mass requires further evaluation. Ultrasound is useful to differentiate between solid and cystic breast masses, especially in young women with dense breast tissue.

- Bilateral mastalgia is rarely associated with breast cancer, but it does not eliminate the possibility. It is usually related to fibrocystic changes in premenopausal women that are associated with diffuse lumpy breasts. A unilateral breast lump with pain must be evaluated for breast cancer.
- Nipple discharge may be from infection which is usually purulent, and from pregnancy, stimulation, or prolactinoma which produces a thin, milky, often bilateral discharge. A pregnancy test may be helpful. A suspicious discharge from a single duct can be evaluated with a ductogram.
- Infectious mastitis and breast abscess, which typically occur in lactating women, appear similar to IBC but are generally associated with fever and leukocytosis (see Chapter 92, Breast Abscess and Mastitis).
- Ductal ectasia with inflammation appears similar but is usually localized.
- Leukemic involvement of the breast may mimic IBC, but the peripheral blood smear is typically diagnostic.

MANAGEMENT

NONPHARMACOLOGIC

- Surgical resection is required in all patients with invasive breast cancer. Oncologic outcomes are similar with mastectomy and breast conserving therapy (lumpectomy plus breast radiation therapy) in appropriately selected patients. For women undergoing mastectomy, breast reconstruction may be performed at the same time as the initial breast cancer surgery, or deferred to a later date.¹⁴ SOR A
- Long-term survival can be achieved in approximately 50% of women with LABC who are treated with a multimodality approach.¹⁵ Prognostic factors include age, menopausal status, tumor stage and histologic grade, clinical response to neoadjuvant therapy, and estrogen receptor status.
- In general, women with IBC are approached similarly to those with noninflammatory LABC except that breast conservation therapy is generally considered inappropriate for these women.¹⁶ SOR A

MEDICATIONS

- Adjuvant systemic therapy consists of administration of hormone therapy, chemotherapy, and/or trastuzumab (a humanized monoclonal antibody directed against HER-2/neu) after definitive local therapy for breast cancer. It benefits most women with early stage breast cancer, but the magnitude of benefit is greatest for those with node-positive disease.¹⁷ SOR A
- The most common approach for advanced breast cancer is preoperative chemotherapy followed by surgery and radiotherapy. Questions regarding sequencing and choice of specific chemotherapy regimens and extent of surgery (including the utility of the sentinel node biopsy) persist. SOR A

FIGURE 93-7 Advanced breast cancer with fungating mass and distortion of the normal breast anatomy. (Courtesy of Kristen Sorensen, MD.)

FIGURE 93-8 Ethiopian woman with breast cancer and five enlarged firm left axillary lymph nodes. Note the breast asymmetry and the peau d'orange skin on the left breast. The dark black area was caused by a "traditional healer" who burned the skin. Unfortunately the woman could not afford to get care at the local hospital, making her prognosis very grave. (Courtesy of Richard P. Usatine, MD.)

- Preoperative (as opposed to postoperative) chemotherapy has several advantages for advanced breast cancer (**Figure 93-7**) treatment. It can reduce the size of the primary tumor, thus allowing for breast conserving surgery, permits assessing an identified mass to determine the sensitivity of the tumor cells to drugs with discontinuation of ineffective therapy (thus avoiding unnecessary toxicity), and enables drug delivery through an intact tumor vasculature.¹⁸ **SOR A**
- Tamoxifen and aromatase inhibitors may be used in selective patients as neoadjuvant hormone therapy of decrease overall tumor volume. **SOR A**

REFERRAL OR HOSPITALIZATION

- With the emergence of breast-conserving therapy (BCT), many women now have the option of preserving a cosmetically acceptable breast without sacrificing survival for early stage invasive breast cancer.

PREVENTION

- Healthy lifestyle choices can decrease the risk of breast cancer, including a low-fat diet, regular exercise, and no more than one drink daily.
- Having children before age 30 years and prolonged breastfeeding may be of help in primary prevention, but will not be a commonly used strategy for most women.
- Secondary prevention involves screening for breast cancer with physical exams and mammography. There is a strong consensus based on consistent findings from multiple randomized trials that routine screening mammography should be offered to women ages 50 to 69 years. Consensus is less strong for routine screening among women ages 40 to 49 years, women older than age 70 years, or for how frequently to screen.
 - The American Cancer Society,¹⁹ the National Cancer Institute,²⁰ the American College of Obstetricians and Gynecologists,²¹ and the National Comprehensive Cancer Network²² recommend starting routine screening at age 40 years.
 - The United States Preventive Services Task Force (USPSTF)²³ and the Canadian Task Force on the Periodic Health Examination²⁴ recommend beginning routine screening at age 50 years.
- Prophylactic mastectomy is an effective and accepted method by some BRCA-positive women after childbearing when their risk of lifetime breast cancer without this intervention is high (e.g., over 60%).
- Chemoprevention with tamoxifen or raloxifene is an option for women who are high risk for breast cancer.

FOLLOW-UP

- Regular follow-up will usually be maintained during treatment. After treatment, life-long regular follow-up for surveillance should be maintained. Metastases can present in many ways including difficulty breathing, back pain, or a new skin nodule (**Figure 93-9**). These complaints should be taken seriously and worked up carefully in any patient with a history of breast cancer.

FIGURE 93-9 Metastatic breast cancer with firm palpable nodules on the back. (Courtesy of Richard P. Usatine, MD.)

PATIENT EDUCATION

- The contralateral breast is at increased risk of breast cancer and should be monitored. Patients on tamoxifen should be monitored for endometrial hyperplasia or cancer.

94 PAGET DISEASE OF THE BREAST

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 62-year-old woman presents with a 6-month history of an eczematous, scaly, rash near her nipple. It is mildly pruritic. On physical examination, the nipple and the areola are involved (**Figure 94-1**). Also, a hard mass is present in the lateral lower quadrant of the same breast. A 4-mm punch biopsy of the affected area including the nipple demonstrates Paget disease. The mammogram is suspicious for breast cancer at the site of the mass and the patient is referred to a breast surgeon.

INTRODUCTION

Paget disease of the breast is a low-grade malignancy of the breast that is often associated with other malignancies. It is an important consideration when working up a chronic persistent abnormality of the nipple.

SYNONYMS

Paget's disease, Mammary Paget disease.

EPIDEMIOLOGY

- The incidence of Paget disease of the breast is approximately 0.6% in women in the United States, according to National Cancer Institute Surveillance, Epidemiology, and End Results (SEER) data.¹ Paget disease, like all breast cancers, is rare in men.
- The peak incidence is between 50 and 60 years of age.²
- It is associated with underlying in situ and/or invasive breast cancer 85% to 88% of the time.³

ETIOLOGY AND PATHOPHYSIOLOGY

- Most patients delay presentation, assuming the abnormality is a benign condition of some sort. The median duration of signs and symptoms prior to diagnosis is 6 to 8 months.²
- Presenting symptoms are sometimes limited to persistent pain, burning, and/or pruritus of the nipple (**Figures 94-1** and **94-2**).
- A palpable breast mass is present in 50% of cases, but is often located more than 2 cm from the nipple–areolar complex.⁴
- Twenty percent of cases will have a mammographic abnormality without a palpable mass, and 25% of cases will have neither a mass nor abnormal mammogram, but will have an occult ductal carcinoma.

FIGURE 94-1 Paget disease of the breast of a 62-year-old woman that presented as a persistent eczematous lesion. (Courtesy of the University of Texas Health Sciences Center, Division of Dermatology.)

FIGURE 94-2 Close-up of Paget disease of the breast. Note the erythematous, eczematous, scaly appearance of the lesion. (Courtesy of the University of Texas Health Sciences Center, Division of Dermatology.)

- In less than 5% of cases, Paget disease of the breast is an isolated finding.⁴
- There are two theories regarding the pathogenesis of Paget disease of the breast, the choice of which affects treatment choices.
 - The more widely accepted epidermotropic theory proposes that the Paget cells arise from an underlying mammary adenocarcinoma that migrates through the ductal system of the breast to the skin of the nipple. It is supported by the fact that Paget disease is usually associated with an underlying ductal carcinoma, and both Paget cells and mammary ductal cells usually express similar immunochemical staining patterns and molecular markers. This could mean that there is a common genetic alteration and/or a common progenitor cell for both Paget cells and the underlying ductal carcinoma.
 - The less widely accepted transformation theory proposes that epidermal cells in the nipple transform into malignant Paget cells, and that Paget disease of the breast represents an independent epidermal carcinoma in situ. It is supported by the fact that there is no parenchymal cancer identified in a small percentage of cases, and underlying breast carcinomas are often located at some distance to the nipple. Most pathologists disagree with the transformation theory.

DIAGNOSIS

CLINICAL FEATURES

- Paget disease of the breast presents clinically in the nipple–areolar complex as a dermatitis that may be erythematous, eczematous, scaly, raw, vesicular, or ulcerated (**Figures 94-1 to 94-4**). The nipple is usually initially involved, and the lesion then spreads to the areola. Spontaneous improvement or healing of the nipple dermatitis can occur and should not be taken as an indication that Paget disease is not present. The diagnosis is made by finding malignant, intraepithelial adenocarcinoma cells on pathology. Rarely, nipple retraction is found.
- Pain, burning, and/or pruritus may be present or even precede clinically apparent disease develops on the skin.

TYPICAL DISTRIBUTION

- Paget disease of the breast is almost always unilateral, although bilateral cases have been reported.
- Work-up must also be directed toward identifying any underlying breast cancer.

LABORATORY TESTING

- The diagnosis is made by finding intraepithelial adenocarcinoma cells (Paget cells) either singly or in small groups within the epidermis of the nipple complex.

IMAGING

- Bilateral mammography is mandatory to assess for associated cancers. MRI may disclose occult cancer in some women with Paget disease of the breast and normal mammography and/or physical examination.⁵

FIGURE 94-3 Paget disease of the breast of a 29-year-old woman that presented as a persistent eczematous lesion for 8 months prior to biopsy. The patient did not have a palpable breast mass. (Courtesy of Richard P. Usatine, MD.)

FIGURE 94-4 Close-up of Paget disease of the breast in the young woman in Figure 94-3. Note the erythematous, scaly, and ulcerated appearance of the lesion. (Courtesy of Richard P. Usatine, MD.)

BIOPSY

- The diagnosis is usually made by full-thickness punch or wedge biopsy that shows Paget cells. Nipple scrape cytology can diagnose Paget disease and may be considered for screening eczematous lesion of the nipple.

DIFFERENTIAL DIAGNOSIS

- Eczema of the areola is the most common cause of scaling of the breast (**Figure 94-5**). If the patient (**Figure 94-5**) had new nipple inversion with the onset of skin changes, this would be more suspicious for Paget disease.
- Bowen disease is squamous cell carcinoma in situ and can differentiate from Paget disease by histology. Also, Bowen disease expresses high-molecular-weight keratins, whereas Paget disease expresses low-molecular-weight keratins (see Chapter 166, Actinic Keratosis and Bowen Disease and Chapter 171, Squamous Cell Carcinoma).
- Superficial spreading malignant melanoma may be confused with Paget disease but histologic study and immunohistochemical staining can separate the two (**Figure 94-6**) (see Chapter 172, Melanoma).
- Seborrheic keratoses and benign lichenoid keratoses can occur on and around the areola and be suspicious for Paget disease (**Figure 94-7**). A biopsy is the best way to make the diagnosis (see Chapter 158, Seborrheic Keratosis).
- Nipple adenoma, which usually presents as an isolated mass with redness, can be diagnosed with biopsy.

MANAGEMENT

SURGICAL

- The treatment and prognosis of Paget disease of the breast is first based on the stage of any underlying breast cancer. Simple mastectomy has traditionally been the standard treatment for isolated Paget disease of the breast, but breast-conserving treatment is being used more often. Breast-conserving surgery combined with breast irradiation is gaining wider acceptance. The surgically conservative approaches include excision of the complete nipple–areolar complex with margin evaluation. Sentinel lymph node biopsy should be performed to evaluate axillary lymph node status.⁶ **SOR B**

PROGNOSIS

- Patients with only noninvasive Paget disease of the nipple have excellent cancer outcome with conservative surgery, with survival rates similar to those achieved with mastectomy.^{7,8} **SOR B** The prognosis of Paget disease with synchronous cancer is dependent upon the tumor stage of the underlying cancer.

PATIENT EDUCATION

- All lesions of the breast that do not heal should be checked for cancer.

FIGURE 94-5 Eczema of the areola in a 43-year-old woman who has had an inverted nipple her whole adult life. She remembers having difficulty breastfeeding her children. The current eczema has been present on the areola on and off for more than 10 years and always responds to topical corticosteroids. Breast examination and mammography are negative. (Courtesy of Richard P. Usatine, MD.)

FIGURE 94-6 Superficial spreading melanoma adjacent to the areola. (Courtesy of the University of Texas Health Sciences Center, Division of Dermatology.)

- The patient's prognosis is based on the underlying cancer, if present, not the Paget disease itself.

MUSCULOSKELETAL PROBLEMS

Strength of Recommendation (SOR)	Definition
A	Recommendation based on consistent and good-quality patient-oriented evidence.*
B	Recommendation based on inconsistent or limited-quality patient-oriented evidence.*
C	Recommendation based on consensus, usual practice, opinion, disease-oriented evidence, or case series for studies of diagnosis, treatment, prevention, or screening.*

*See Appendix A on pages 1447–1450 for further information.

95 ARTHRITIS OVERVIEW

Heidi Chumley, MD
Richard P. Usatine, MD

PATIENT STORY

A 50-year-old woman presents with new complaint of pain in several fingers. She has had psoriasis for many years; however, she only developed joint pain last year. Her examination is significant for swelling and tenderness at the distal interphalangeal (DIP) joints of her second, third, and fourth fingers (**Figure 95-1, A**). She had an elevated erythrocyte sedimentation rate (ESR) and radiographs with erosive changes (**Figure 95-1, B**). Choices for therapy include methotrexate and the new biologic anti-tumor necrosis factor (TNF)- α medications.

INTRODUCTION

Arthritis means joint inflammation of the joints; however, the term is used for any disease or condition that affects joints or the tissues around the joints. Joint pain can be classified as monoarticular or polyarticular and inflammatory or noninflammatory. Diagnosis is based on a combination of clinical presentation, synovial fluid analysis, other laboratory tests, and radiographic findings. Management goals include minimizing joint damage, controlling pain, maximizing function, and improving quality of life.

EPIDEMIOLOGY

- Fifty million adults in the United States (22%) report doctor-diagnosed arthritis.¹
- Arthritis is the most common cause of disability in the United States. Twenty-one million adults have functional limitations because of arthritis.¹
- Fifty percent of adults age 65 years or older have been diagnosed with arthritis.¹
- One in every 250 children younger than the age of 18 have some form of arthritis.²
- In 2003, the total cost attributable to arthritic conditions was \$128 billion.³

ETIOLOGY AND PATHOPHYSIOLOGY

Arthritis can be caused by one of several mechanisms.

- Noninflammatory arthritis (i.e., osteoarthritis) is caused by bony overgrowth (osteophytes) and degeneration of cartilage and underlying bone (**Figures 95-2 and 95-3**).
- Autoimmune arthritis (i.e., rheumatoid arthritis, systemic lupus erythematosus [SLE], psoriatic arthritis) is caused by an inappropriate immune response.

FIGURE 95-1 Psoriatic arthritis at initial presentation in a 50-year-old woman with psoriasis and new-onset hand pain. **A**. Note the prominent involvement of the distal interphalangeal joints. **B**. Radiography showing early psoriatic arthritis changes with periarticular erosions seen at the distal interphalangeal joints. (Courtesy of Richard P. Usatine, MD.)

- Crystalline arthritis (i.e., gout, calcium pyrophosphate dehydrate deposition disease) is caused by deposition of uric acid crystals (gout) or calcium pyrophosphate dehydrate crystals (CPPD) resulting in episodic flares with periods of remission.
- Septic arthritis is most commonly caused by bacteria (*Neisseria gonorrhoeae*, *Staphylococcus*, or *Streptococcus*; also gram-negative bacilli in immunocompromised patients and *Salmonella* in patients with sickle cell disease). Several viral illnesses may also have an associated arthritis.
- Postinfectious (reactive) arthritis is caused by an immune reaction several weeks after a urethritis or enteric infection.
- Fibromyalgia has an unknown etiology but includes abnormal pain perception processing.

DIAGNOSIS

CLINICAL FEATURES

- Two features help limit the differential diagnosis: mono- or polyarticular and inflammatory or noninflammatory.
 - Monoarticular noninflammatory—Osteoarthritis, trauma, atrioventricular node (AVN).
 - Monoarticular inflammatory—Infectious (gonococcal, nongonococcal, Lyme disease) or crystalline (gout or CPPD).
 - Polyarticular noninflammatory—Osteoarthritis.
 - Polyarticular inflammatory—Rheumatologic (rheumatoid arthritis [RA], SLE, psoriatic, ankylosing spondylitis [AS], and others) or infectious (bacterial, viral, postinfectious) or crystalline later in the disease.

TYPICAL DISTRIBUTION

- Most commonly affected joints
 - Osteoarthritis (see Chapter 96, Osteoarthritis)—Knees, hips, hands (DIP and proximal interphalangeal [PIP]), and spine (**Figures 95-2 to 95-4**).
 - RA (see Chapter 97, Rheumatoid Arthritis)—Wrists, metacarpophalangeal (MCP), PIP, metatarsophalangeal (MTP) early in the disease with larger joints affected later in the disease (**Figures 95-5 and 95-6**). Rheumatoid nodules may be found over the fingers, hands, wrists, or elbows (**Figures 95-6 and 95-7**).
 - SLE—Hands, wrists, and knees (see Chapter 180, Lupus: Systemic and Cutaneous) (**Figure 95-8**).
 - AS—Lower back and hips, costosternal junctions, shoulders (see Chapter 98, Ankylosing Spondylitis).
 - Psoriatic arthritis—Hands, feet, knees, spine, sacroiliac; typically with a personal or family history or psoriasis (**Figures 95-9 to 95-11**); **Table 95-1** describes the five types of psoriatic arthritis.
 - Gonococcal—Migratory with a single joint affected, such as knee, wrist, ankle, hand, or foot.
 - Lyme disease—Knee and/or other large joints.
 - Gout (see Chapter 100, Gout)—Begins as monoarticular with MTP joint of the first toe; hands, ankles, tarsal joints, and knee may also be affected (**Figures 95-12 to 95-14**); gout may present with tophi over any joint; olecranon bursitis can also be the result of gout (**Figure 95-15**).

FIGURE 95-8 Longstanding lupus erythematosus has caused swan-neck deformities without bone erosions. This is called Jaccoud arthropathy and is caused by synovitis and inflammatory capsular fibrosis. (Courtesy of Everett Allen, MD.)

FIGURE 95-6 Rheumatoid arthritis involving the whole upper-extremity joints with nodules on the elbow, wrist, and hand joints. (Courtesy of Ricardo Zuniga-Montes, MD.)

FIGURE 95-9 Psoriatic arthritis of both knees. This patient has asymmetric psoriatic arthritis in his hands. (Courtesy of Richard P. Usatine, MD.)

FIGURE 95-7 Rheumatoid arthritis with rheumatoid nodules over the MCP joints along with deformities of the digits. (Courtesy of Ricardo Zuniga-Montes, MD.)

FIGURE 95-10 Psoriatic arthritis with dactylitis and significant distal interphalangeal joint involvement. Note the destruction of the nails. Almost all patients with psoriatic arthritis have nail involvement. (Courtesy of Ricardo Zuniga-Montes, MD.)

TABLE 95-1 Five Types of Psoriatic Arthritis (PsA)

Type	Characteristics
Symmetric arthritis	Affects approximately 15% of PsA patients. Involves multiple symmetric pairs of joints in the hands and feet; resembles rheumatoid arthritis.
Asymmetric arthritis	The most common type of PsA, found in approximately 80% of patients. Usually involves only 1–3 joints in an asymmetric pattern and may affect any joint (e.g., knee, hip, ankle, and wrist). Hands and feet may have enlarged “sausage” digits.
Distal interphalangeal predominant (DIP)	This “classic type” occurs in only approximately 5% of PsA patients. Primarily involves distal joints of the fingers and toes. It is sometimes confused with osteoarthritis, but nail changes are common in PsA.
Spondylitis (Axial)	Inflammation of the spinal column causing a stiff neck and pain in the lower back and sacroiliac area. Peripheral disease may be seen in the hands, arms, hips, legs, and feet.
Arthritis mutilans	A severe, deforming type of PsA affecting <5% of patients with PsA. Usually affects a few joints in the hands and feet. Has been associated with pustular psoriasis.

Adapted from Van Voorhees A, Feldman SR, Koo JYM, et al; National Psoriasis Foundation: *The Psoriasis and Psoriatic Arthritis Pocket Guide: Treatment Algorithms and Management Options*, 3rd ed. <http://www.psoriasis.org/document.doc?id=354>.

- CPPD—Knee, but also seen in shoulder, elbow, wrist, hands, and ankle joints; most patients have polyarticular disease.
- Septic arthritis can involve any joint; acute onset of pain, swelling, and joint immobility; fever may be present; must be recognized and treated immediately as joint destruction occurs within days (**Figure 95-16**).

LABORATORY TESTING

- Not indicated for noninflammatory arthritis.
- Inflammatory polyarthritis: Use laboratory tests to supplement the clinical impression. Initial tests to consider include:
 - ESR or C-reactive protein as a nonspecific measure of inflammation.
 - Rheumatoid factor or anti-CCP (anti-cyclic citrullinated peptide) antibody when RA is expected. Anti-CCP antibody is more sensitive and specific than rheumatoid factor.
 - Antinuclear antibody (ANA), anti-double-stranded DNA (dsDNA) and anti-Ro when SLE is expected.
 - Human leukocyte antigen (HLA)-B27 when AS is expected.
 - Serum uric acid can be used, especially to follow hypouricemic therapy; levels can be normal or low during an attack.
- Joint aspiration:
 - Synovial fluid analysis is critical when septic or crystalline arthritis are suspected.
 - Assess for clarity/color, cell count, crystals, and culture. Gram stain may give quick information, but a culture should also be done. If there is clinical suspicion for septic arthritis, empiric antibiotics should be started even if the Gram stain is negative.
 - White blood cell (WBC)—Normal <200 cells/ μL ; noninflammatory arthritis <2000 cells/ μL ; inflammatory, crystalline, or septic arthritis >2000 cells/ μL , often 30,000 to 50,000 cells/ μL .
 - Crystals—Monosodium urate (gout) are needle-shaped and negatively birefringent; CPPD are rhomboid-shaped positively birefringent.
 - Culture—Gonococcal arthritis synovial fluid cultures can be negative in two-thirds of cases (synovial biopsy is positive);

FIGURE 95-11 Psoriatic arthritis mutilans with severe destruction of the fingers. (Courtesy of Ricardo Zuniga-Montes, MD.)

FIGURE 95-12 An acute gouty arthritis attack of multiple finger joints in a 75-year-old man with gout. His joints have been painful for 3 weeks. The erythema of the acute inflammation is evident. (Courtesy of R. Treadwell, MD.)

tuberculosis, fungal, and anaerobic infections may also be difficult to identify on culture.

IMAGING

- Osteoarthritis—Osteophytes, sclerosis, narrowed joint space (**Figure 95-17**).
- Rheumatoid arthritis—Soft-tissue swelling, erosions, and loss of joint space; severe destruction and subluxation in advanced disease. MRI changes may appear first and include synovitis, effusions, and bone marrow changes.
- SLE—Soft-tissue swelling; erosions are rare and joint deformities are uncommon.
- AS—Symmetric sacroiliitis, erosions, sclerosis; active sacroiliitis is best seen on MRI.
- Psoriatic arthritis—Erosions with adjacent proliferation, “pencil-in-cup” deformity, osteolysis, digit telescoping, asymmetric sacroiliitis.
- Gout—Only soft-tissue swelling until advanced disease when erosions with sclerotic margins may be present.
- CPPD—Can mimic other types of arthritis; chondrocalcinosis, linear or punctate radiodense deposits in cartilage or menisci may be present.

Table 95-2 provides a comparison of psoriatic arthritis with RA, osteoarthritis, and AS.

DIFFERENTIAL DIAGNOSIS

- Bursitis is inflammation of a bursa. Pain and tenderness is localized to the bursa. Common locations include subdeltoid, trochanteric, olecranon.
- Tendinitis is inflammation of a tendon that produces a localized pain aggravated by stretching of the affected tendon.
- Inflammatory myopathy or myositis is inflammation of the muscle most commonly caused by an autoimmune or infectious process. Pain is in the muscles instead of the joints.
- Polymyalgia rheumatica is a systematic inflammatory disease with aching and stiffness in the torso and proximal extremities. Pain is in the muscles, but synovitis or tenosynovitis may also be present. Passive joint range of motion is preserved. ESR is elevated. Normocytic anemia and thrombocytosis can be present.
- Fibromyalgia—Widespread pain not limited to joints. Joint swelling is absent. Laboratory tests and imaging if obtained are normal.

MANAGEMENT

The goals of treatment are to control pain, maximize function, improve quality of life, and, for inflammatory causes, minimize joint damage.

NONPHARMACOLOGIC

- Recommend an exercise program. Aerobic exercise, strength training, or both improves pain and function in arthritis and other rheumatic diseases.⁴ **SOR A**

FIGURE 95-13 Severe tophaceous gout with chronic gouty arthritis causing hand deformities and disabilities. (Courtesy of Jack Resneck, Sr., MD.)

FIGURE 95-14 Severe tophaceous gout with large tophi and joint destruction of the hands. (Courtesy of Ricardo Zuniga-Montes, MD.)

- Splints or braces may be used to offload stress on a particular joint.
- Weight loss reduces joint load for weight-bearing joints.

MEDICATIONS

See specific chapters.

REFERRAL OR HOSPITALIZATION

- Hospitalize patients with suspected septic arthritis and begin empiric therapy with appropriate intravenous antibiotics.
- Refer patients in whom the diagnosis is unclear, especially if RA is suspected as early diagnosis and treatment improves outcomes.
- Refer patients in whom surgical management is indicated.

PROGNOSIS

Prognosis depends on the type of arthritis as well as psychosocial factors and socioeconomic status.

FOLLOW-UP

Acute arthritis should be followed closely until resolution. Chronic arthritis is managed as other chronic diseases with the frequency of follow-up dependent upon the type of arthritis and the severity of the disease.

PATIENT EDUCATION

For chronic arthritic conditions, the goals of treatment are to control pain, maximize function, improve quality of life and minimize joint damage. Self-management is an important part of chronic arthritic conditions.

96 OSTEOARTHRITIS

Jana K. Zaudke, MD
Heidi Chumley, MD

PATIENT STORY

A 70-year-old woman presents with pain and swelling in the joints of both hands, which impedes her normal activities. Her pain is better in the morning after resting and worse after she has been working with her hands. She denies stiffness. On examination, you find bony enlargement of some distal interphalangeal (DIP) and proximal interphalangeal (PIP) joints on both hands (**Figure 96-1**). Radiographs confirm the presence of Heberden and Bouchard nodes. She begins taking 1 g of acetaminophen twice a day and has significant improvement in her pain and function.

INTRODUCTION

Osteoarthritis is the most common type of arthritis. It involves degeneration of the articular cartilage accompanied by osteophytes (hypertrophic bone changes) around the joints. Osteoarthritis leads to pain in the joints with movement and relief with rest.

SYNONYMS

Degenerative joint disease.

EPIDEMIOLOGY

- Osteoarthritis is the most common type of arthritis, affecting 10% of men and 13% of women age 60 years or older.^{1,2}
- Incidence and prevalence will likely increase given the obesity epidemic and the aging of the population.²
- In the Framingham cohort (mean age 71 years at baseline) women and men developed symptomatic knee osteoarthritis at the rate of 1% and 0.7% per year, respectively.¹
- Risk of developing osteoarthritis increases with knee injury in adolescence or adulthood (relative risk [RR] = 2.95) and obesity (RR = 1.51 to 2.07).¹
- Occupational physical activity and abnormal joint loading also increase the risk.^{1,2}

ETIOLOGY AND PATHOPHYSIOLOGY

- Biomechanical factors and inflammation upset the balance of articular cartilage biosynthesis and degradation.
- Chondrocytes attempt to repair the damage; eventually, however, enzymes produced by the chondrocytes digest the matrix and accelerate cartilage erosion.

FIGURE 96-1 Bony enlargement of some distal interphalangeal (DIP) and proximal interphalangeal (PIP) joints consistent with Heberden (DIP) and Bouchard (PIP) nodes. (Courtesy of Richard P. Usatine, MD.)

- Inflammatory molecules related to cytokine production, prostaglandin and arachidonic acid metabolism may be involved in susceptibility to osteoarthritis.³

RISK FACTORS

- Advanced age.
- Female gender.
- Genetics.
- Obesity.
- Knee injury in adolescence and adulthood.
- Abnormal joint loading.
- Occupational history.

DIAGNOSIS

The American College of Rheumatology uses the following criteria for the most common joints involved in osteoarthritis.

- Knee—Knee pain, osteophytes on radiograph, and 1 of 3: age older than 50 years, stiffness less than 30 minutes, or crepitus on physical examination (sensitivity = 91%, specificity = 86%).⁴
- Hip—Hip pain and 2 of 3: erythrocyte sedimentation rate (ESR) less than 20 mm/h; femoral or acetabular osteophytes by radiograph; superior, axial, or medial joint space narrowing by radiograph (sensitivity = 89%, specificity = 91%).⁵
- Hand—Hand pain, aching, or stiffness and 3 of 4: hard tissue enlargement of 2 or more DIP joints, fewer than 3 swollen metacarpophalangeal (MCP) joints, hand tissue enlargement of 2 or more selected joints, deformity of 1 or more selected joints. Selected joints include second and third DIP, second and third PIP, first carpometacarpal (CMC) on both hands (sensitivity = 94%, specificity = 87%).⁶

CLINICAL FEATURES

- Typically, joint pain is worsened with movement and relieved by rest. A small subset may demonstrate inflammatory symptoms including prolonged stiffness.
- Loss of function (i.e., impaired gait with knee or hip osteoarthritis, impaired manual dexterity with hand osteoarthritis).
- Radicular pain when vertebral column osteophytes impinge nerve roots.
- Bony enlargement of the DIP joints (Heberden nodes) or PIP joints (Bouchard nodes) (**Figure 96-1**).

TYPICAL DISTRIBUTION

Most common joints affected include knees, hands, hips, and back.

LABORATORY TESTING

- Not typically indicated. Normal ESR and synovial fluid white blood cell count (WBC) less than 2000/mm.^{3,4}
- Imaging.
- Loss of joint space or osteophytes on radiographs (**Figures 96-2** to **96-5**).

FIGURE 96-2 Joint space narrowing, marginal osteophytes, and Heberden nodes at the distal interphalangeal joints of the second through fifth fingers. (Courtesy of Heidi Chumley, MD.)

FIGURE 96-3 Osteoarthritis of the knee causing joint space narrowing, sclerosis, and bony spurring in all 3 compartments of the right knee, most pronounced in the medial compartment. (Courtesy of Heidi Chumley, MD.)

DIFFERENTIAL DIAGNOSIS

Musculoskeletal pain can also be caused by:

- Connective tissue diseases (scleroderma and lupus) that have other specific systemic signs.
- Fibromyalgia—Pain at trigger points instead of joints.
- Polyarticular gout—Erythematous joints and crystals in joint aspirate (see Chapter 100, Gout).
- Polymyalgia rheumatica—Proximal joint pain without deformity, elevated ESR.
- Seronegative spondyloarthropathies—Asymmetric joint involvement, spine often involved (see Chapter 98, Ankylosing Spondylitis).
- Reactive arthritis—History of infection, sexually transmitted disease, or bowel complaints. The patient may have conjunctivitis, iritis, urethritis in addition to joint pain and arthritis (see Chapter 155, Reactive Arthritis).
- Rheumatoid arthritis—Symmetric soft-tissue swelling in distal joints, stiffness after inactivity, positive rheumatoid factor. Ulnar deviation of the fingers at the MCP joints is a distinct finding in rheumatoid arthritis (**Figure 96-6**; Chapter 97, Rheumatoid Arthritis).
- Bursitis—Pain at one site, often increased with direct pressure.

FIGURE 96-4 Articular space narrowing, sclerosis, and subchondral cyst formation of both hips because of osteoarthritis. (From Chen MYM, Pope TL Jr, Ott DJ. *Basic Radiology*. New York NY: McGraw-Hill; 2004:189, Figure 7-34.)

MANAGEMENT

NONPHARMACOLOGIC

Table 96-1 lists the nonpharmacologic options for management of osteoarthritis.

- Recommend therapeutic land-based or aquatic exercise to maintain range of motion and strengthen muscles surrounding affected joints.^{7,9} **SOR A**
- Recommend weight loss for knee or hip osteoarthritis. Weight loss may not improve current pain, but may slow progression and can be recommended for numerous other health reasons.⁹ **SOR C**
- Consider a knee brace that alters knee mechanics (i.e., Counter-Force brace).¹⁰ **SOR B**

MEDICATIONS

Table 96-2 lists the pharmacologic therapy for osteoarthritis.

- Prescribe acetaminophen (2 to 4 g/day) for pain relief in patients at higher risk for GI complications. In a pooled analysis, acetaminophen improved pain by 5%, number needed to treat (NNT) 4 to 14.⁸ **SOR A**
- Prescribe a NSAID for moderate to severe hip or knee osteoarthritis in patients who are at low risk for GI complications. GI bleeding is a significant risk to many elderly patients with osteoarthritis (see **Table 96-3**). A 2006 Cochrane review found NSAIDs were slightly more effective than acetaminophen, although more likely to produce adverse GI events.⁸ **SOR A**

FIGURE 96-5 Loss of disc space and facet arthropathy at L5-S1 and small osteophytes, best seen on L4 and L5. These changes are caused by osteoarthritis. (Courtesy of Heidi Chumley, MD.)

- If NSAIDs are to be used in patients with risk factors (see **Table 96-3**), consider giving a misoprostol or a proton pump inhibitor for protection.⁹ Note that H₂-blockers may decrease gastric symptoms from NSAIDs but are not protective against GI bleeding.
- Consider opioid analgesics for patients with severe osteoarthritis who have not responded to NSAIDs (be careful to not prescribe narcotics to patients in recovery from substance abuse).⁹ **SOR C**
- Consider a topical NSAID rather than an oral NSAID for hand or knee osteoarthritis, especially in patients 75 years of age or older. **SOR C** There is not yet enough data to recommend topical NSAID for hip osteoarthritis.⁹
- Consider topical capsaicin 0.025% cream 4 times a day for hand osteoarthritis.² **SOR B**
- Consider an intraarticular corticosteroid injection for acute pain related to knee or hip osteoarthritis.^{9,11} **SOR B**
- Consider an intraarticular hyaluronic injection for symptomatic chronic knee osteoarthritis. A 2006 Cochrane review of 76 clinical trials concluded that these injections were effective for treating knee osteoarthritis.¹¹ **SOR A**

COMPLEMENTARY AND ALTERNATIVE THERAPY

- Consider participation in tai chi programs for knee or hip osteoarthritis.⁹
- Consider traditional Chinese acupuncture or transcutaneous electrical stimulation for patients with knee osteoarthritis who choose not to have or are not candidates for a total-knee arthroplasty.⁹
- In their newest guidelines, the American College of Rheumatology does not recommend use of chondroitin sulfate and glucosamine for osteoarthritis.⁹

TABLE 96-1 Nonpharmacologic Options for Osteoarthritis

Weight loss (if overweight)
Aerobic exercise
Range-of-motion exercises
Muscle-strengthening
Assistive devices for walking
Yoga and Tai Chi
Safe shoes
Lateral-wedged insoles (for genu varum) bracing
Physical and Occupational therapy
Joint protection such as braces
Assistive devices for activities of daily living
Arthritis Foundation Self-Management Program
Social support

FIGURE 96-6 Rheumatoid arthritis showing ulnar deviation of the fingers at the metacarpophalangeal joints. (Courtesy of Richard P. Usatine, MD.)

TABLE 96-2 Pharmacologic Options for Osteoarthritis

Oral
• Acetaminophen
• COX-2-specific inhibitor
• NSAID plus a proton pump inhibitor
• Opioids (e.g. hydrocodone)
• Salsalate
• Tramadol
Topical
• Methylsalicylate
• Topical NSAID (e.g diclofenac gel)
Intraarticular
• Glucocorticoids (e.g. triamcinolone)
• Hyaluronic acid

REFERRAL

Refer patients who do not respond to conservative therapy to:

- Any physician with experience doing joint injections if this is not within your skillset.
- Rheumatologist for evaluation and treatment.
- Orthopedic surgeon for evaluation for arthroplasty or joint replacement.

FOLLOW-UP

There are no recommended intervals for follow-up; however, it is reasonable to see patients periodically to assess pain management and function.

PATIENT EDUCATION

Osteoarthritis is a chronic, progressive disease. Nonpharmacologic and pharmacologic therapies can reduce pain and preserve function.

97 RHEUMATOID ARTHRITIS

Heidi Chumley, MD

PATIENT STORY

A 79-year-old woman with late-stage rheumatoid arthritis comes for routine follow-up (**Figures 97-1 to 97-4**). She began having hand pain and stiffness approximately 40 years ago. She took nonprescription medications for pain for approximately 10 years before seeing a physician. She was diagnosed with rheumatoid arthritis on the basis of combination of clinical, laboratory, and radiograph findings. She was treated with prednisone and tried most of the disease-modifying agents as they became available; however, her disease progression continued. Approximately 10 years ago, she began having increased foot pain and difficulty walking. Today, she works with a multidisciplinary team to control pain and preserve hand function and independence.

INTRODUCTION

Rheumatoid arthritis (RA) is a progressive chronic illness that causes significant pain and disability. RA is a polyarticular inflammatory arthritis that causes symmetrical joint pain and swelling and typically involves the hands. Early recognition and treatment with nonbiologic and/or biologic disease-modifying antirheumatologic agents (DMARDs) can induce remission and preserve function.

EPIDEMIOLOGY

- RA is found in 0.8% of the adult population worldwide.¹
- It is more than twice as common in women as compared to men (54 per 100,000 vs. 25 per 100,000).¹
- Typical age of onset is 30 to 50 years.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- Genetic predisposition coupled with an autoimmune or infection-triggering incident.
- Synovial macrophages and fibroblasts proliferate, leading to increased lymphocytes and endothelial cells.
- Increased cellular material occludes small blood vessels, causing ischemia, neovascularization, and inflammatory reactions.
- Inflamed tissue grows irregularly, causing joint damage.
- Damage causes further release of cytokines, interleukins, proteases, and growth factors, resulting in more joint destruction and systemic complications including a higher risk for cardiovascular disease

RISK FACTORS

Genetic predisposition signified by a positive family history.

FIGURE 97-1 Ulnar deviation at metacarpophalangeal joints in advanced rheumatoid arthritis. Also note the swelling at the distal interphalangeal joints, seen best on the first finger. (Courtesy of Richard P. Usatine, MD.)

FIGURE 97-2 Rheumatoid arthritis in the foot of a 79-year-old woman with subluxation of the first metatarsophalangeal joint. (Courtesy of Richard P. Usatine, MD.)

DIAGNOSIS

The 2010 American College of Rheumatology/European League Against Rheumatism classification criteria uses a scoring system to designate patients as definite RA. A score of 6 or greater out of 10 meets criteria for definite RA.²

- Joint involvement—1 large joint (0 points); 2 to 10 large joints (1 point); 1 to 3 small joints with or without large joints (2 points); 4 to 10 small joints with or without large joints (3 points); more than 10 joints with at least 1 small joint (5 points).
- Serology—Negative rheumatoid factor (RF) and anticitrullinated protein antibody (ACPA) (0 points); low positive RF or ACPA (2 points); high positive RF or ACPA (3 points).
- Acute-phase reactants—Normal C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) (0 points); abnormal CRP or ESR (1 point).
- Duration of symptoms—Less than 6 weeks (0 points); 6 or more weeks (1 point).

American Rheumatism Association criteria (with positive likelihood ratio abbreviated as LR+):³

- Stiffness around joint for 1 hour after inactivity (LR+1.9).
- Three or more of these have soft-tissue swelling—Wrist, proximal interphalangeal (PIP), metacarpophalangeal (MCP), elbow, knee, ankle, metatarsophalangeal (MTP) (LR+1.4).
- Hand joints involved (LR+1.5) (**Figures 97-1, 97-4, and 97-5**).
- Symmetrical involvement of one of these: wrist, PIP, MCP, elbow, knee, ankle, MTP (LR+1.2).
- Subcutaneous nodules (LR+3.0) (**Figures 97-5 and 97-6**).
- Positive serum RF (LR+8.4).
- Osteopenia or erosion of surrounding joints on hand or wrist films (LR+11) (**Figures 97-7 and 97-8**).

CLINICAL FEATURES

Joint pain and swelling, polyarticular and symmetrical.

TYPICAL DISTRIBUTION

- Hands are typically involved (**Figures 97-1, 97-4, and 97-5**).
- Commonly involved joints include wrist, PIP, MCP, elbow, knee, ankle, MTP.
- Subcutaneous nodules (**Figures 97-5 and 97-6**).

LABORATORY TESTING

- RF (negative in 30% of patients; positive in many connective tissue, neoplastic, and infectious diseases).
- ACPA, high specificity, often present before definitive diagnosis can be made; presence predicts arthritis development.
- CRP (>0.7 pg/mL) or ESR (>30 mm/h).
- Complete blood count (normocytic or microcytic anemia, thrombocytosis).

FIGURE 97-3 Deviation at the metatarsophalangeal joints from bony destruction in advanced rheumatoid arthritis. (Courtesy of Richard P. Usatine, MD.)

FIGURE 97-4 Ulnar deviation at metacarpophalangeal joints seen in a 79-year-old woman with advanced rheumatoid arthritis. (Courtesy of Kelly Foster, MD.)

IMAGING

- Hand or wrist radiographs may show soft tissue swelling, osteopenia, erosions, subluxations, and deformities (**Figures 97-7 and 97-8**).

DIFFERENTIAL DIAGNOSIS

RA can mimic many systemic diseases and should be differentiated from the following:¹

- Connective tissue diseases (scleroderma and lupus), which have other specific systemic signs.
- Fibromyalgia—Pain at trigger points instead of joints.
- Hemochromatosis—Abnormal iron studies and skin changes.
- Infectious endocarditis—Heart murmurs, high fever, risk factors, such as IV drug use.
- Polyarticular gout—Erythematous joints and crystals in joint aspirate.
- Polymyalgia rheumatica—Proximal joint pain without deformity.
- Seronegative, spondyloarthropathies—Asymmetric joint involvement, spine often involved.
- Reactive arthritis—History of infection, sexually transmitted disease, or bowel complaints.

MANAGEMENT

Target outcome is remission through use of disease-modifying agents.

Monitor for complications:

- Patients with RA are twice as likely to have serious GI complications; monitor carefully.
- Anemia—Twenty-five percent will respond to iron therapy.
- Cancer—Twofold increase risk of lymphomas and leukemias.
- Cardiac complications such as pericarditis or pericardial effusion (30% at diagnosis).
- Cervical spine disease—Atlas instability; careful with intubation and avoid flexion films after trauma until atlas visualized.

NONPHARMACOLOGIC

- Use of multidisciplinary team improves outcomes.⁴ **SOR B**
- Exercise improves aerobic capacity and strength without increases in pain or disease activity.⁵ **SOR B**

MEDICATIONS

- NSAIDs can be used for pain control,⁵ **SOR A** but do not alter disease progression and should not be used alone.
- Systemic corticosteroids relieve pain and slow progression,⁵ **SOR A** but have serious side effects and should be used at lowest dose possible with added bone protection (e.g., calcium and vitamin D or a bisphosphonate).
- Nonbiologic DMARDs such as methotrexate, leflunomide, hydroxychloroquine, sulfasalazine, and minocycline reduce disease

FIGURE 97-5 Rheumatoid nodules in the hands. (Courtesy of Richard P. Usatine, MD.)

FIGURE 97-6 Rheumatoid nodules on the arm of a patient with rheumatoid arthritis. (Courtesy of Richard P. Usatine, MD.)

progression and should be considered in all patients without contraindications. **SOR A**

- Biologic DMARDs, such as antitumor necrosis factor (TNF) drugs, rituximab, abatacept, adalimumab, etanercept, and infliximab, reduce disease progression and should be considered in patients with high disease activity and poor prognostic features. **SOR C**

COMPLEMENTARY AND ALTERNATIVE THERAPY

- Diet modifications—Omega-3 polyunsaturated fatty acids may decrease antiinflammatory medication use.¹ **SOR B**

REFERRAL

- Refer patients with new diagnosis of or with a suspicion of RA to a physician experienced in the use of nonbiologic and biologic DMARDs.

Recommendations for initiating DMARDs are based on:⁶

- Disease duration.
- Presence of poor prognostic factors (functional limitations, extraarticular disease, positive RF and/or anti-CCP [anti-cyclic citrullinated peptide], bony erosions).
- Classification of low, moderate, or high disease activity, based on one of several validated instruments (e.g., Rheumatoid Arthritis Disease Activity Index).

DMARDs reduce disease progression, but have several contraindications and must be followed closely.

- Do not start nonbiologic or biologic DMARDs when the patient has an active bacterial infection, active or latent (before preventive therapy is initiated) tuberculosis (TB), acute hepatitis B or C, active herpes zoster, or a systemic fungal infection.⁶
- Avoid DMARDs if white blood cell count (WBC) is less than 3000/mm³ or platelets are under 50,000/mm³, New York Heart Association class III or IV heart failure, or liver transaminases more than twice the normal value.⁶
- Start methotrexate or leflunomide monotherapy for any disease duration, with or without poor prognostic factors, and any classification of disease activity.⁶
- Combination DMARD therapy (e.g., methotrexate [MTX] and sulfasalazine) may be used in patients with any duration of disease, poor prognostic features, and moderate or high disease activity.⁶
- Consider biologic DMARDs for patients with any disease duration, high disease activity, and poor prognostic features. Etanercept, infliximab, and adalimumab improve function and quality of life as monotherapy or in combination with nonbiologic DMARDs.⁶

PROGNOSIS

- Poor prognostic features include functional limitations, extraarticular disease, positive RF and/or anti-CCP [anti-cyclic citrullinated peptide], and bony erosions.⁶
- RA patients have an increased risk of cardiovascular disease.

(From Brunnicardi CF, Andersen DK, Billiar TR, et al. *Schwartz's Principles of Surgery*. New York: McGraw-Hill; 2005:1666, Figure 42-40. Copyright 2005.)

FOLLOW-UP

Multidisciplinary follow-up with primary care, rheumatologist, occupational and physical therapists, and patient educators improves outcomes.

PATIENT EDUCATION

RA is a chronic illness. Twenty percent to 40% of patients will have remission with therapy. Early treatment can prevent complications and allow the person to maintain function. It is best to stay active and exercise to the best of your ability.

PATIENT RESOURCES

- Information on RA is available at <http://www.rheumatoid-arthritis.com/ra/> and <http://www.ra.com/>.

98 ANKYLOSING SPONDYLITIS

Heidi Chumley, MD

PATIENT STORY

A 43-year-old man falls and presents with acute back and diffuse abdominal pain. He has had back pain on and off for years. Also, his wife notes that he has become “stooped” forward in the last few years. The radiographs show flowing ligamentous ossification and syndesmophyte formation about the cervical, thoracic, and lumbar spine consistent with ankylosing spondylitis (bamboo spine) (**Figure 98-1**). The KUB (kidneys, ureters, bladder) view film also shows fusion of the sacroiliac joints consistent with ankylosing spondylitis (**Figure 98-2**). No fracture, dislocation, or abdominal pathology is identified. The patient’s symptoms are treated and nonsteroidal antiinflammatory drugs (NSAIDs) are started. On follow-up a blood test reveals that he is human leukocyte antigen (HLA)-B27–positive.

INTRODUCTION

Ankylosing spondylitis is an inflammatory disease of the axial spine associated with the HLA-B27 genotype. Symptoms of low back and/or hip pain begin in late adolescence or early adulthood. Diagnosis is based on clinical features and radiographic findings.

EPIDEMIOLOGY

- Prevalence in general population is approximately 0.2% to 0.5%.
- Five percent of patients in primary care with low back pain have a spondyloarthritis, a spectrum of diseases that includes ankylosing spondylitis.¹
- More common in males than in females (approximate ratio: 4:1).
- Ninety percent of patients are HLA-B27–positive.² However, many people with HLA-B27 do not develop the disease.

ETIOLOGY AND PATHOPHYSIOLOGY

- Inflammatory arthritis with a poorly understood pathology.
- Environment and genetic factors result in inflammation.
- Chronic inflammation causes in extensive new bone formation.

RISK FACTORS

- Male gender.
- HLA-B27–positive genotype.

FIGURE 98-1 A. Fusion of the vertebral bodies and posterior elements gives the spine the classic “bamboo” appearance seen in ankylosing spondylitis. B. Note the marked kyphosis and the syndesmophytes that are the thin vertical connections between the anterior aspects of the vertebral bodies. They are located in the outer layers of the annulus fibrosus. (Courtesy of Richard P. Usatine, MD.)

FIGURE 98-2 KUB view showing bamboo spine and fusion of both sacroiliac joints. (Courtesy of Richard P. Usatine, MD.)

DIAGNOSIS

Mean delay of 7 to 8 years until diagnosis. Consider screening patients younger than 45 years of age with chronic low back pain for more than 3 months.³

CLINICAL FEATURES

- Younger patient (younger than 40 years of age at start of disease).
- Inflammatory (pain and stiffness worsen with immobility and improve with motion; symptoms are worse at night or early morning).
- Good response to NSAIDs—Sensitivity = 77%, specificity = 85%, positive likelihood ratio (LR+) 5.1.¹
- Symptoms of inflammatory back pain have fair sensitivity (75%) and specificity (75%). LR+ 3.1. Number needed to screen is 7.^{1,3}

PHYSICAL EXAM

- Limited range of motion of the spine.
- Tenderness over the spine and sacroiliac joints.
- In the advanced stages, kyphosis may occur with a stooped posture (**Figure 98-1**).
- Uveitis of the eye is the most common extraarticular manifestation occurring in 20% to 30% of patients. This can present with a red painful eye along with photophobia. The involved eye may have an irregular pupil and a 360-degree perilimbal injection (see Chapter 18, Uveitis and Iritis).

TYPICAL DISTRIBUTION

- Pain in lower back and/or sacroiliac joints.

LABORATORY TESTING

- HLA-B27 has good sensitivity (90%) and specificity (90%). LR+ 9.0. Number needed to screen is 3. Test is expensive.^{1,3}
- May also consider HLA-B27 for patients with inflammatory back pain only.¹

IMAGING

- Radiologic findings confirm the diagnosis; however, these may occur years after the onset of symptoms.
- Plain films—Typical spinal features include erosions, squaring, sclerosis, syndesmophytes, and fractures; may also see sacroiliac joint fusion (**Figure 98-3**). Flowing ligamentous ossification and syndesmophyte formation about the cervical, thoracic, and lumbar spine form the classic bamboo spine described in ankylosing spondylitis (**Figures 98-1** and **98-2**).
- MRI—Detects inflammation, such as acute sacroiliitis, which occurs prior to bony change visible by radiographs.

DIFFERENTIAL DIAGNOSIS

Causes of back pain in patients younger than age 45 years:

- Lumbar strain or muscle spasm—Acute onset often with precipitating event.

FIGURE 98-3 Ankylosing spondylitis with near fusion of right sacroiliac (SI) joint and pseudowidening (from erosive changes) of the left SI joint. (Courtesy of Everett Allen, MD.)

- Herniated disc—Acute onset with pain radiating below the knee into lower leg or foot with numbness, weakness, and/or loss of ankle jerk reflex.
- Vertebral fractures—Risk factors are osteoporosis or significant trauma.
- Abdominal pathology such as pancreatitis—Associated with GI symptoms.
- Kidney diseases—Nephrolithiasis (pain radiating into groin); pyelonephritis (fever, nausea, and urinary symptoms).
- Osteoarthritis—Worse after working; less commonly has inflammatory symptoms.
- Other spondyloarthritis (SpA) include psoriatic spondyloarthritis (**Figure 98-4**), SpA associated with inflammatory bowel disease, reactive SpA, and undifferentiated SpA.

MANAGEMENT

- NSAIDs and physical therapy reduce pain. Continuous NSAIDs reduce radiographic progression.⁴ **SOR B**
- Disease-modifying antirheumatic drugs (methotrexate, leflunomide) have not been demonstrated to have patient-oriented outcomes.⁴ **SOR B**
- Tissue necrosis factor blockers are recommended for patients who fail NSAIDs and physical therapy. Consider treating or referring for treatment with shorter duration of symptoms, elevated acute phase reactants (i.e., C-reactive protein), or rapid radiographic progression. **SOR C**
 - Infliximab improves pain scores and quality of life within 2 weeks (61% vs. 19% placebo).⁴ **SOR B** Many relapse; high cost, but economic analysis is favorable compared to estimated cost of loss of function.⁴
 - Adalimumab improves quality-of-life and function scores by 12 weeks. Improvement continues for up to a year and remains stable through 3 years.⁵ **SOR B**
 - Etanercept improves pain scores (60% vs. 12%).⁴ **SOR B** Relief within 2 weeks. Many relapse; reinitiation works.⁴ Seventy-six percent of patients treated with Etanercept, compared to 53% of patients treated with sulfasalazine, improved by 20% within 4 months.⁶ Improvements in pain, function, and mobility were sustained at 5 years.⁷

PROGNOSIS

Mortality is increased in male patients with ankylosing spondylitis. Leading cause of death was cardiovascular. Risk factors for reduced survival include absence of NSAID use (odds ratio [OR] 4.35), work disability (OR 3.65), increased C-reactive protein (OR 2.68), and diagnostic delay (OR 1.05).⁸

FOLLOW-UP

Follow patients for progression of pain or decreased function using standard ankylosing spondylitis, such as the Ankylosing Spondylitis

FIGURE 98-4 Psoriatic arthritis showing swan-neck deformities, involvement of proximal interphalangeal (PIP) and distal interphalangeal (DIP) joints and skin plaques. (Courtesy of Richard P. Usatine, MD.)

Disease Activity Score or the Bath Ankylosing Spondylitis Disease Activity Index or Functional Index.

PATIENT EDUCATION

Ankylosing spondylitis is a chronic disease. NSAIDs and physical therapy and exercise are important in controlling pain and slowing progression of disease. If these are ineffective, tissue necrosis factor blockers are effective; however, these are expensive and pain recurs when they are stopped.

99 BACK PAIN

Heidi Chumley, MD

PATIENT STORY

A 60-year-old woman presents with chronic low back pain that began many years ago. Her back pain waxes and wanes and she has taken acetaminophen and ibuprofen with some relief. About 3 months ago, she began to have daily pain. She recalls no trauma. Her examination is unremarkable other than some decreased flexion. Straight leg raise test is negative. As the patient is older than 55 years of age, radiographs are ordered and they demonstrate degenerative changes in her lumbar spine (**Figure 99-1**). She is started on scheduled acetaminophen and ibuprofen along with an exercise program.

INTRODUCTION

Back pain is one of the most common reasons that adults see their physician. Most acute back pain is a result of mechanical causes. Serious pathology can be recognized by the presence of red flags. Acute back pain is treated with reassurance, returning to activities, and acetaminophen with or without an NSAID. Psychological factors increase the risk of development of chronic pain. Chronic back pain is difficult to treat and the best outcomes are typically achieved by an interprofessional team.

EPIDEMIOLOGY

- Six percent of visits to primary care physicians are for back pain.¹
- Low back pain 1-year incidence is 20% and 1-year prevalence is 40% in adults.²
- Thoracic back pain 1-year prevalence is 15% to 27% in adults.³
- Treatment for back and neck problems accounted for approximately \$86 billion in health care expenditures in the United States in 2005.⁴
- Prevalence of malignancy in patients with LBP presenting to a primary care office or emergency room is 0.1% to 1.5%.⁵

ETIOLOGY AND PATHOPHYSIOLOGY

- LBP can be caused by pain in the muscles, ligaments, joints, bones, discs, nerves, or blood vessels.²
- In 90% of cases, the specific cause of LBP is unclear.²
- In 10% of cases, a specific cause such as an infection, fracture, or cancer is identified.

RISK FACTORS

- Older age—Prevalence of LBP increases with age into the sixth decade.²

FIGURE 99-1 Lateral view shows grade 1 degenerative spondylolisthesis at L4-L5 (arrow), moderate facet osteoarthritis of L5-S1. Marked T12-L1 disc degeneration (arrowhead) and mild L4-L5 disc degeneration.

- Low educational status.²
- Occupational factors—Manual labor, bending, twisting, and whole-body vibration.²
- Psychosocial factors increase the risk of transition from acute to chronic pain.²
- Risk factors for cancer—Previous history of cancer (positive likelihood ratio [LR+] 23.7), elevated erythrocyte sedimentation rate (ESR) (LR+ 18.0), reduced hematocrit (LR+ 18.3).⁵

DIAGNOSIS

The diagnosis can be classified into three categories:

1. Nonspecific back pain—Pain for less than 6 weeks (acute), 6 to 12 weeks (subacute), or more than 12 weeks (chronic); negative straight-leg raise test; absence of red flags.
2. Radicular syndrome—LBP with radiation down leg; positive straight-leg raise test; absence of red flags.
3. Serious pathology—Further work-up required for presence of red flags, including age younger than 20 or older than 55 years; significant trauma; fever; unexplained weight loss; neurologic signs of cauda equina; progressive neurologic deficit.

TYPICAL DISTRIBUTION

Lumbar pain is about twice as common as thoracic pain.

LABORATORY TESTING

Helpful in the presence of red flags:

- Complete blood count (CBC) to evaluate for anemia (malignancy) or leukocytosis (infection).
- Consider human leukocyte antigen (HLA)-B27 in younger patients with inflammatory symptoms.

IMAGING

- In acute back pain without red flags, imaging can be delayed for 6 weeks.
- Radiographs may show degenerative joint disease changes in osteoarthritis; vertebral fractures; malignancies; and findings of ankylosing spondylitis including erosions, sclerosis, syndesmophytes (see Chapter 98, Ankylosing Spondylitis).
- MRI is the best imaging test for disc herniation and imaging of the spinal cord. Emergent MRI is indicated in patients with suspected spinal cord compromise or cauda equina syndrome.
- CT myelogram is a useful alternative to evaluate disc herniation in patients who cannot undergo MRI.

DIFFERENTIAL DIAGNOSIS

- Osteoporotic vertebral fracture—Acute onset of pain, typically seen in older patients or those at risk for osteoporosis, point tenderness at the level of the fracture, confirmation by plain radiographs demonstrating compression or burst fracture (**Figure 99-2**).

FIGURE 99-2 Lateral view demonstrating the loss of vertebral body height seen with a compression fracture deformity (*arrow*) of the superior end plate of the L2 vertebral body. There is also a mild concave compression deformity of the superior end plate of the L5 vertebral body.

- Spinal stenosis—Pain worse with extension, presence of unilateral or bilateral leg symptoms worse with walking and better with sitting, confirmation by CT or MRI.
- Herniated disc—Radicular pain that is worse with flexion or sitting, may be accompanied by numbness or weakness of foot plantar flexion (L5/S1) or dorsiflexion (L4/L5), MRI confirms the level and shows the type of herniation (**Figures 99-3** and **99-4**).
- Spinal infection/abscess—Most commonly seen in patients who use IV drugs, have diabetes mellitus, have cancer, or have a transplant; symptoms include fever, night pain, night sweats, and elevated ESR. MRI is the study of choice. If neurologic deficit is present, obtain an urgent MRI to evaluate for an abscess, which would require hospitalization and consultation with a spinal surgeon.
- Ankylosing spondylitis (see Chapter 98, Ankylosing Spondylitis)—Pain, most commonly in the low back or sacroiliac joints, usually begins in late adolescence or early adulthood. Pain and stiffness worsen with immobility and improve with motion. HLA-B27 may be positive. Radiographic findings confirm the diagnosis, but occur years after symptoms.
- Malignancy—Typically seen in an older patient; symptoms of weight loss and night pain; significant anemia; history of cancer; nonresponse to therapy. Often seen on plain radiographs. Bone scan is the most sensitive test.
- Abdominal pathology such as pancreatitis, pyelonephritis, and cholecystitis can present as back pain or pain radiating to the back.

MANAGEMENT

ACUTE BACK PAIN

Most national guidelines agree on the following:⁶

- Nonpharmacologic:
 - Reassure patients without red flags that they do not have a serious condition, advise them to remain active, discourage bed rest, and encourage an early return to work while back pain is still present.
 - Exercise is considered no more effective than return to normal activities for LBP within the first 4 to 6 weeks.⁶
- Medications:
 - Acetaminophen
 - Add NSAID if needed (ask about GI problems and protect against ulcers as needed).
 - Consider a short course of opiates or muscle relaxers if pain is severe and inadequately treated with acetaminophen and NSAIDs.
 - Consider antidepressants (such as amitriptyline) or anticonvulsants (such as gabapentin) for radicular pain.
- Complementary and alternative therapy:
 - National guidelines differ; some recommend and some do not recommend spinal manipulative therapy for acute back pain.
 - Spinal manipulative therapy has a similar effect on pain relief and functional status as other interventions.⁷
- Referral or hospitalization:
 - Patients with cauda equina syndrome should have expedient imaging and urgent referral to a spinal surgeon.

FIGURE 99-3 MRI showing herniated nucleus pulposus (arrow) at L5-S1 in a patient with radicular pain and a poor response to 6 weeks of conservative therapy.

FIGURE 99-4 MRI cross section demonstrates that the herniated disc (arrow) is compressing S1 nerve root.

- Refer patients with serious pathology such as infection, tumor, or fracture to appropriate consultants.

SUBACUTE (6 TO 12 WEEKS) OR CHRONIC (>12 WEEKS) BACK PAIN

Most national guidelines agree on these recommendations:⁶

- Nonpharmacologic:
 - Encourage an exercise program.
 - Recommend cognitive-behavioral therapy.
 - Discourage ultrasound or electrotherapy.
- Medications:
 - National guidelines vary on medication recommendations.
 - Start with acetaminophen then add NSAIDs if needed.
 - Consider adding one of these medications: tramadol, an antidepressant, a benzodiazepine, or an opiate.
- Complementary and alternative therapy:
 - Yoga—There have been a number of randomized controlled trials (RCTs) and metaanalyses that have found yoga to be an excellent treatment for chronic and recurrent LBP.¹⁻⁴ **SOR A**
A 12-week yoga program for adults with chronic or recurrent LBP led to greater improvements in back function than did usual care.⁴ Yoga classes were more effective than a self-care book, but not more effective than stretching classes, in improving function and reducing symptoms caused by chronic LBP, with lasting benefits.³
- Referral or hospitalization:
 - Chronic pain is difficult to treat. Use an interdisciplinary team to maximize effectiveness if possible.
 - Consider referring patients who do not respond to conservative therapy to a pain management specialist or a spine surgeon.

PREVENTION

Good posture, appropriate lifting techniques, maintaining a healthy weight, and enjoying an active lifestyle may help prevent back pain. Adding yoga to an active lifestyle has the potential to prevent recurrent back pain and diminish the pain of chronic back pain.¹⁻⁴ **SOR A**

PROGNOSIS

- Patients with nonradicular acute back pain—By 12 months, 40% recover fully.⁸
- Patients with acute back pain that have psychological factors at baseline are more likely to develop chronic LBP.⁹

FOLLOW-UP

Follow-up is determined by etiology. Patients with acute back pain, without red flags, especially those at risk to develop chronic pain, should be followed closely. Patients with chronic pain benefit from ongoing treatment by an interprofessional team.

PATIENT EDUCATION

- Reassure patients without red flags that most acute back pain is not a result of a serious cause and can be treated conservatively.
- Advise patients with chronic back pain that a comprehensive approach to pain management is more likely to result in pain improvement than medications alone.
- Yoga and stretching can be a valuable adjunct to other treatments.¹⁻⁴

100 GOUT

Mindy A. Smith, MD
Heidi Chumley, MD

PATIENT STORY

A 91-year-old woman arrives by ambulance to the emergency department because she was experiencing severe pain in her right middle finger (**Figure 100-1**). History reveals that she has had swelling of her finger for approximately 1 year. Palpation of the distal interphalangeal joint demonstrated firmness rather than fluctuance. A radiograph of the finger was ordered (**Figure 100-2**). The radiograph and physical examination are consistent with acute gouty arthritis superimposed on tophaceous gout. The diagnosis was confirmed by an aspirate of the finger that demonstrated negatively birefringent, needle-like crystals, both intracellularly and extracellularly. She was given 1.2 mg of colchicine followed by a second dose of 0.6 mg after 1 hour. Her pain was markedly decreased in 4 hours. Her serum uric acid level was determined to be 10.7 mg/dL. The colchicine was used in this case because the risk of using NSAIDs was considered to be high because of her previous history of gastric bleeding secondary to NSAIDs.

INTRODUCTION

Gout is an inflammatory crystalline arthritis. Elevated uric acid leads to deposition of monosodium urate (MSU) crystals in the joints resulting in a red, hot, swollen joint. Gout typically begins as a monoarthritis, but can become polyarthritic. Treatment of acute episodes include NSAIDs, colchicine, or intraarticular steroids. Chronic therapy includes lowering the uric acid level using dietary modifications and urate-lowering drugs.

EPIDEMIOLOGY

- Gout affects 1% to 2% of the U.S. population and approximately 6% of men older than 80 years of age.¹
- Gout is more prevalent in men than women.
- Gout usually begins after age 30 years in men and after menopause in women; it is familial in approximately 40% of patients.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- Defective uric acid metabolism with inefficient renal urate excretion leads to underexcretion of uric acid and an elevated serum uric acid level.
- Overproduction of uric acid, instead of underexcretion, occurs in approximately 10% of patients with gout, and also leads to elevated serum uric acid levels.

FIGURE 100-1 Acute gouty arthritis superimposed on tophaceous gout. (Courtesy of Geiderman JM. An elderly woman with a warm, painful finger. *West J Med.* 2000;172(1):51-52.)

- Elevated serum uric acid leads to deposition of MSU crystals in the joints and the kidneys.
- Crystals trigger proinflammatory cytokines, which cause local inflammation, tissue necrosis, fibrosis, and subchondral bone destruction.

RISK FACTORS

- Medications that cause hyperuricemia—Thiazide diuretics, cyclosporine, aspirin (<1 g/day).²
- Conditions associated with gout—Insulin resistance, obesity, hypertension, hypertriglyceridemia, hypercholesterolemia, congestive heart failure, renal insufficiency, early menopause, organ transplant.^{2,3}
- Dietary—Increased intake of meat and seafood, alcohol, soft drinks, and fructose.²

DIAGNOSIS

Diagnostic characteristics useful in predicting gout, based on the 1977 criteria developed by the American College of Rheumatology, are:

- Monoarthritis.
- Redness over the joints.
- First metatarsophalangeal (MTP) joint involved (**Figure 100-3**).
- Unilateral first MTP joint attack.
- Unilateral tarsal joint attack.
- Tophi identified (**Figures 100-1, 100-4, and 100-5**).
- Hyperuricemia.
- Asymmetric swelling in joint on radiograph.
- Subcortical cysts on radiograph.
- MSU crystals in joint fluid (**Figure 100-6**).
- Joint fluid culture negative.

The presence of 6 of these 11 criteria helps confirm gout (positive likelihood ratio [LR+] 20, negative likelihood ratio [LR−] 0.02).⁴

CLINICAL FEATURES

- Gout usually begins at night as an acute attack over several hours.
- Fever, chills, and arthralgias sometimes precede gout.
- The affected joint is swollen, red, hot, and painful to touch and movement (**Figures 100-1, 100-3, and 100-6**). Symptoms subside in 3 to 10 days.
- Dietary or alcohol excess, trauma, surgery, and serious medical illness can precipitate gout attacks.

TYPICAL DISTRIBUTION

Initially, only one joint may be affected, but other joints commonly involved are fingers and toes (75%) and knees and ankles (50%).

- The most common site is the first MTP joint and the name for gout at this site is podagra (**Figure 100-3**).
- Joint involvement is often asymmetric.

FIGURE 100-2 This x-ray of the finger in **Figure 100-1** shows several tophi (monosodium urate [MSU] deposits) in the soft tissue over the third distal interphalangeal joint. Note the typical punched out lesions under the tophi. This is subchondral bone destruction. (Courtesy of Geiderman JM. An elderly woman with a warm, painful finger. *West J Med.* 2000;172(1):51-52.)

FIGURE 100-3 Podagra. Typical inflammatory changes of gout at first MTP joint. (Courtesy of Richard P. Usatine, MD.)

FIGURE 100-4 A. A 52-year-old homeless man with acute monoarticular gouty arthritis presenting with knee pain and swelling. Knee aspiration revealed a straw-colored effusion. B. With light microscopy numerous refractile needle-shaped crystals of uric acid were visualized in the joint fluid. The arrow points to a cluster of needle-shaped uric acid crystals. (Reproduced with permission from Usatine RP, Sacks B, Sorci J. A swollen knee. *J Fam Pract.* 2003;52(1):53-55. Reproduced with permission from Frontline Medical Communications.)

FIGURE 100-5 Severe tophaceous gout causing major deformities in the hands. (Courtesy of Eric Kraus, MD.)

FIGURE 100-6 Tophaceous deposits on both elbows and one finger in a man with gout. (Courtesy of Richard P. Usatine, MD.)

- Tophi may be seen at the MTP joint, elbow, hands, and ears (Figures 100-1, 100-4, and 100-5).

LABORATORY TESTING

- Serum uric acid is often elevated, but is variable from week to week and normal in 25% of patients with gout.
- Measure 24-hour urine for excretion of uric acid.
- On microscopy, the presence of MSU crystals from synovial fluid or a tophus that are negatively birefringent in polarized light (yellow against a red background) helps to confirm the diagnosis, but there are limited data on the accuracy of crystal identification.
- Even with light microscopy refractile needle-shaped crystals of uric acid can be visualized in the joint fluid (Figure 100-6).

IMAGING

Although radiographs are negative early in the disease, punched-out erosions (“rat bites”) are seen later and can be diagnostic, especially if seen adjacent to tophi (Figure 100-2).

DIFFERENTIAL DIAGNOSIS

In addition to gout, the differential diagnosis of inflammatory monoarthritis includes the following:

- Cellulitis—Joint motion is not painful; synovial culture is negative (see Chapter 120, Cellulitis).
- Septic arthritis—Fever; painful motion; synovial fluid has many white blood cells and a positive culture.
- Rheumatic arthritis—Symmetric joint involvement (usually hands); slow onset; synovial culture is negative (see Chapter 97, Rheumatoid Arthritis).
- Pseudogout—Findings like gout; synovial fluid with short rods; crystal refraction blue on red background (calcium pyrophosphate dihydrate).

MANAGEMENT

ACUTE GOUT

- Prescribe an NSAID, such as indomethacin 50 to 75 mg every 6 to 8 hours, in patients without renal impairment (serum creatinine should be <2) or peptic ulcer disease.⁵ SOR B
- Colchicine can be used in patients who cannot take NSAIDs. Colchicine 1.2 mg followed by 0.6 mg after 1 hour has equivalent efficacy and lower side effects compared to a high dose of 4.8 mg given over 6 hours. One third of patients will respond.⁶ SOR B
- In monoarticular gout, consider an intraarticular injection with long-acting steroid (e.g., triamcinolone acetonide, 10 to 40 mg, depending on the size of the joint).⁵ SOR C

CHRONIC GOUT

The treatment of chronic gout includes modifications in diet and existing medications (if possible) and lowering urate levels.

Treatment measures include:¹

- Nonpharmacologic:
 - Reduce the intake of purine-rich foods (e.g., organ meats, red meats, and seafood).
 - Increase fluid intake to 2000 mL/day.
 - Lower alcohol intake.
 - Consume dairy products as these may be protective against gout.¹
- Medications:
 - Change medications—Discontinue aspirin (low dose up to 2 g/day causes uric acid retention) and consider stopping a thiazide diuretic.
 - Lower urate levels with xanthine oxidase inhibitors (e.g., allopurinol), uricosuric agents (e.g., probenecid) or uricase agents (e.g., pegloticase).
 - The level of urinary uric acid helps to determine which medication should be used with levels ≥ 600 mg/24 hours indicating a need to halt production with xanthine oxidase inhibitors and levels less than 600 mg/24 hours indicating a need for uricosuric drugs.
 - Allopurinol (100 to 300 mg/day for mild gout; for patients with moderate to severe tophaceous gout give 400 to 600 mg/day with a maximum daily dose of 800 mg/day). Titrate allopurinol to a serum uric acid level less than 6.⁷ **SOR B**
 - Give colchicine (0.6 mg twice daily for the first 6 months of therapy) concomitantly during initiation of allopurinol to reduce the frequency and severity of acute flares.⁸ **SOR B**
 - Consider uricosuric agents (probenecid, 250 mg twice daily increasing to 2 to 3 g/day or sulfinpyrazone, 50 to 100 mg twice daily increasing to 200 to 400 mg twice daily) in patients with uric acid excretion of less than 600 mg/24 hours, with normal renal function, younger than age 60 years, and no history of renal calculi.⁵ **SOR C**
 - Consider oral potassium citrate (10 to 20 mEq 3 to 4 times a day) to prevent crystal precipitation in the urine as uricosuric agents increase urinary uric acid excretion.
 - Pegloticase, a mammalian recombinant uricase, is a medication that degrades urate when administered by intravenous infusion. Early randomized controlled trials show improvements in pain and quality of life; however, adverse events are high. This may be an option for patients with severe gout, allopurinol intolerance or refractoriness, and serum uric acid greater than 8 mg/dL despite conventional therapy.⁹
- Complementary and alternative therapy:
 - A number of Chinese and Vietnamese medicinal plants and herbs have xanthine oxidase inhibitory activity, but few have been tested for clinical effectiveness.

PREVENTION

- Intake of dairy products, folate, and coffee lowers risk of gout.³

- In a patient with a prior episode of gout, avoid medications that cause hyperuricemia—Thiazide diuretics, cyclosporine, aspirin (<1 g/day).²

PROGNOSIS

- Untreated, recurrent, and more severe attacks are common with 60% of patients experiencing a recurrence in year 1 and 25% in year 2.
- Colchicine 0.5 mg up to 3 times a day decreases attacks, but may not decrease joint destruction.⁷ **SOR B**

FOLLOW-UP

- Follow patients with an acute flare through resolution and initiation of prophylactic therapy if indicated.

PATIENT EDUCATION

Advise patients to lose weight, minimize alcohol use, eat less meat and seafood, and obtain more protein from dairy.⁵

101 OLECRANON BURSTITIS

Heidi Chumley, MD

PATIENT STORY

A 60-year-old man presents with swelling in his elbow for the last 2 months. He does not have pain unless he leans on his elbow. He denies any trauma. **Figure 101-1** demonstrates a “goose egg” swelling over the olecranon bursa that is not warm and is tender only to palpation. He has full range of motion. His olecranon bursitis was treated with ice, rest, and NSAIDs and he was told to avoid leaning on his elbow.

INTRODUCTION

Olecranon bursitis can be aseptic, from repetitive trauma or systemic disease, or septic, most commonly from Gram-positive bacteria. Differences in clinical presentation help differentiate aseptic from septic olecranon bursitis; however, analysis of fluid may be necessary. Aseptic olecranon bursitis is treated with an elbow pad, NSAIDs, and ice. Septic olecranon bursitis is treated with drainage and antibiotics.

SYNONYMS

Popeye elbow, student elbow, baker elbow.

EPIDEMIOLOGY

Prevalence of aseptic olecranon bursitis is unknown, but is estimated to be twice as common as septic olecranon bursitis.¹

- Prevalence of septic olecranon bursitis is at least 10 per 100,000 in the general population.²
- Peak age of onset is 40 to 50 years.
- Eighty-one percent are male.
- Fifty percent have antecedent trauma.

ETIOLOGY AND PATHOPHYSIOLOGY

Inflammation or degeneration of the sac overlying the olecranon bursa from:

- Repetitive motion or trauma, such as direct pressure on the elbow.
- Systemic diseases such as gout, pseudogout, and rheumatoid arthritis.
- Infection, typically by *Staphylococcus aureus* or another Gram-positive organism.

FIGURE 101-1 Chronic aseptic olecranon bursitis in a 60-year-old man showing typical swelling over the olecranon. There is no erythema or tenderness. (Courtesy of Richard P. Usatine, MD.)

RISK FACTORS

- Aseptic bursitis—Occupation-related activities such as leaning on the elbow.
- Septic bursitis—Immunocompromised state.

DIAGNOSIS

The diagnosis of olecranon bursitis is made clinically, by its typical appearance (**Figures 101-1** and **101-2**). When necessary, joint aspiration verifies the diagnosis and separates septic from aseptic bursitis.

CLINICAL FEATURES OF SEPTIC BURSTITIS²

- Common symptoms—Pain (87%), redness (77%), and subjective fever or chills (45%).
- Common signs—Erythema (92%), swelling (85%), edema (75%), tenderness (59%), and fluctuance (50%).
- Less common signs—Decreased range of motion (27%) and temperature greater than or equal to 37.8°C (100.04°F) (20%).

CLINICAL FEATURES OF ASEPTIC BURSTITIS

- Swelling with minimal pain and tenderness.
- Erythema may be present (**Figure 101-2**).
- Fever is typically absent.

LABORATORY TESTING

- Erythrocyte sedimentation rate and C-reactive protein may be elevated in both septic and aseptic presentations.³
- Bursal fluid findings that help differentiate septic from aseptic olecranon bursitis:³
 - White blood cell (WBC) count greater than 30,000 in septic bursitis; less than 28,000 in aseptic bursitis; however, elevated WBC count is also seen in rheumatoid arthritis or gout.
 - Neutrophils seen in septic bursitis; monocytes seen in aseptic bursitis.
 - Glucose less than 50% of serum glucose in septic bursitis; greater than 70% of serum glucose in aseptic bursitis.
 - Gram-positive organisms on gram stain in septic bursitis.

IMAGING

- Usually not indicated.
- In traumatic bursitis, radiographs may identify a foreign body.
- In atypical cases, MRI may be needed to determine the extent of soft-tissue involvement.

ASPIRATION

- Aspirate when there is suspicion of infection or crystal disease (moderate pain, fever, warmth over the olecranon)⁴ or for discomfort caused by extensive swelling.⁵

FIGURE 101-2 Aseptic olecranon bursitis secondary to repetitive elbow leaning in this computer programmer. There is some erythema and minimal tenderness. The aspirated fluid was clear. Most patients (70%) retain full extension in the elbow despite swelling over the olecranon. (Courtesy of Richard P. Usatine, MD.)

DIFFERENTIAL DIAGNOSIS

Pain and swelling around the elbow joint may be caused by:

- Gout or pseudogout (acute pain with signs of inflammation), prior history of gout (pseudogout).
- Rheumatoid arthritis (pain, inflammation, loss of range of motion, often involves other joints).
- Septic joint (acute pain, loss of range of motion, fever).
- Hemorrhage into the bursa (history of trauma, bruising).

Other causes of elbow pain typically without swelling include:

- Lateral or medial epicondylitis (pain lateral or medial, not over olecranon).
- Ulnar nerve entrapment (concurrent numbness in fingers).

MANAGEMENT

SEPTIC BURSTITIS

- Identify organism using Gram stain and culture (**Figure 101-3**).
- If the WBC is slightly elevated and no organisms are seen on Gram stain, treat empirically with oral antibiotics active against Gram positives until culture results are available (i.e., cephalexin 500 mg twice a day or levofloxacin 500 mg/day).⁶ **SOR C**
- If WBCs are moderately elevated and organisms are seen on Gram stain, use intravenous medications such as oxacillin or nafcillin 2 g every 6 hours or cephazolin 1 to 2 g every 8 hours.⁶ **SOR C**
- Vancomycin can be considered for penicillin- or cephalosporin-allergic patients or in communities with high rates of methicillin-resistant *S. aureus* (MRSA).⁶ **SOR C**
- Home IV therapy is safe and effective for immunocompetent patients.² **SOR B**
- Hospitalize immunosuppressed patients or those who do not respond to therapy.⁶ **SOR C**
- Aspirate after several days of treatment and continue antibiotics for 5 days after fluid is sterile.⁶ **SOR C**
- Refer to an orthopedic specialist if incision and debridement of the bursa is needed. **SOR C**

ASEPTIC BURSTITIS

- The first line of treatment should be wearing an elbow pad at all times in addition to modification of activities (no leaning on elbows) and NSAIDs as tolerated.
- Patient education about aggravating factors.
- Ice and rest.
- Consider corticosteroid injection for severe pain, persistent, or recurrent fluid accumulation.⁶ **SOR C** Because there is a risk of converting an aseptic olecranon bursitis to a septic one with aspiration and steroid injection, the treatment options noted above should be exhausted prior to consideration of steroid injection.
- Consider surgical referral for recalcitrant fluid accumulation.

FIGURE 101-3 Septic olecranon bursitis in an immunosuppressed patient with pemphigus vulgaris. Aspiration showed gram positive cocci on gram stain and MRSA grew out of the culture. Patient was treated in the hospital with IV vancomycin and then discharged on oral doxycycline when the sensitivities were available and the patient was stable. (Courtesy of Richard P. Usatine, MD.)

ASPIRATION

When indicated, aspirate fluid as follows:⁵

- Flex elbow to 45 degrees.
- Locate triangle formed by lateral olecranon, the head of the radius, and the lateral epicondyle.
- Using sterile technique, insert needle into the soft tissue in the middle of the triangle, pointing toward the medial epicondyle. (If there is a significant amount of fluid, it is hard to miss the fluid regardless of the direction of the needle as long as the needle gauge is sufficient for aspiration. Consider a 20- to 22-gauge needle, and if an 18-gauge needle is to be used, give the patient some local anesthetic first.
- Aspirate fluid and send for complete blood count (CBC), Gram stain, culture, and evaluate for crystals if gout or pseudogout is expected.
- Consider injecting with steroid (see below) only if aspirate is clear and history does not suggest infection.

PROGNOSIS

- Aseptic olecranon bursitis often resolves with conservative therapy.⁷
- Septic bursitis has a recurrence rate of 15% in hospitalized patients treated with surgical interventions and antibiotics.⁷

FOLLOW-UP

Follow septic bursitis until fluid is sterile. Reaspirate after 4 to 5 days of antibiotics and continue antibiotics for 5 days after fluid is sterile.

PATIENT EDUCATION

Limit bursa aggravation by not leaning on elbows or pushing off on elbows when arising. Aseptic and septic bursitis may require multiple aspirations.

102 CLAVICULAR FRACTURE

Heidi Chumley, MD

PATIENT STORY

A 17-year-old boy presents after falling off his skateboard and landing directly on his lateral shoulder. He had immediate pain and swelling in the middle of his clavicle. His examination revealed a bump in the middle of his clavicle. A radiograph confirmed a midclavicular fracture (**Figure 102-1**). He was treated conservatively with a sling, which he wore for approximately 1 of the recommended 3 weeks. A follow-up radiograph demonstrated good healing. The bump on his clavicle is still palpable; however, this does not bother him.

INTRODUCTION

Clavicular fractures are common in both children and adults and are most commonly caused by accidental trauma. The clavicle most commonly fractures in the midshaft (**Figures 102-1 to 102-3**), but can also fracture distally (**Figure 102-4**). Many fractures can be treated conservatively. Refer patients with significant displacement or distal fractures for surgical evaluation.

EPIDEMIOLOGY

- Clavicular fractures account for 2.6% of all fractures in adults, with an overall incidence of 64 per 100,000 people per year; midshaft fractures account for approximately 69% to 81% of all clavicle fractures.¹
- Accounts for 10% to 15% of fractures in children; 90% are midshaft fractures.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Most are caused by accidental trauma from fall against the lateral shoulder or an outstretched hand or direct blow to the clavicle; however, stress fractures in gymnasts and divers have been reported.
- Pathologic fractures (uncommon) can result from lytic lesions, bony cancers or metastases, or radiation.
- Birth trauma (neonatal).
- Physical assaults, intimate partner violence, and child abuse can cause clavicular fractures.

DIAGNOSIS

CLINICAL FEATURES

- History of trauma with a mechanism known to result in clavicle fractures (i.e., fall on an outstretched hand or lateral shoulder, or direct blow).

FIGURE 102-1 Midshaft clavicle fracture. Clavicle fractures are designated midshaft (in the middle third), distal (distal third), or medial (medial third). (From Simon RR, Sherman SC, Koenigsnecht SJ. *Emergency Orthopedics the Extremities*. New York, NY: McGraw-Hill; 2007:286, Fig. 11-35. Copyright 2007.)

FIGURE 102-2 Midshaft clavicle fracture with angulation. (From Simon RR, Sherman SC, Koenigsnecht SJ. *Emergency Orthopedics the Extremities*. New York, NY: McGraw-Hill; 2007:297, Fig. 11-54. Copyright 2007.)

TABLE 102-1 Typical Distribution/Classification

Group (Approx. %)	Fracture Location	Radiographic Appearance
Group I (80%)	Middle third	Upward displacement (Figures 102-1 to 102-3)
Group II (15%)	Distal third	Medial side of fragment is displaced upward (Figure 102-4)
Type I		Minimal displacement
Type II		Fracture medial to coracoclavicular ligaments; some overlapping of fragments
Type III		Fracture at the articular surface of the acromioclavicular (AC) joint; can look like AC separation
Group III (5%)	Medial third	Medial side of fragment up; distal side down

- Pain and swelling at the fracture site.
- Gross deformity at site of fracture.

TYPICAL DISTRIBUTION

- For the typical distribution and classification of clavicular fractures, see **Table 102-1**.

IMAGING

- Obtain plain films of the clavicle for radiographic evidence of fracture.

FIGURE 102-3 Midshaft clavicular fracture with proximal fragment displaced superiorly from the pull of the sternocleidomastoid muscle. (From Simon RR, Sherman SC, Koenigsknecht SJ. *Emergency Orthopedics the Extremities*. New York, NY: McGraw-Hill; 2007:283, Fig. 11-32. Copyright 2007.)

DIFFERENTIAL DIAGNOSIS

- Acromioclavicular (AC) separation (**Figure 102-5**)—Fall directly on the “point” of the shoulder or a direct blow, pain with overhead movement, tenderness at the AC joint, and AC joint separation on radiographs.
- Sternoclavicular dislocation—Fall on the shoulder, chest and shoulder pain exacerbated by arm movement or when lying down, and a prominence from the superomedial displacement of the clavicle (uncommon).
- Pseudoarthrosis of the clavicle—Painless mass in the middle of the clavicle from failure of the central part of the clavicle to ossify (extremely rare).

MANAGEMENT

For all adults and children:

- Assess neurovascular status of injured extremity.
- Assess for damage to lungs (pneumothorax or hemothorax).
- Determine the classification and amount of displacement by radiograph (**Figure 102-1**; see also **Table 102-1**).

NONPHARMACOLOGIC

Most clavicular fractures can be treated nonoperatively, other options include fixation with plates or pins.

FIGURE 102-4 Distal clavicular fracture. (From Simon RR, Sherman SC, Koenigsknecht SJ. *Emergency Orthopedics the Extremities*. New York, NY: McGraw-Hill; 2007:286, Fig. 11-35. Copyright 2007.)

Child clavicle fracture

- Treat most children with any type of clavicle fracture conservatively, without immobilization.² **SOR C**
- Treat children nonoperatively even with 90-degree displacement and several inches of overlap.² **SOR C**

Adult midclavicular fractures

- Treat adults with non- or minimally displaced midshaft clavicular fractures nonoperatively. **SOR B**
- Place adults in a sling instead of a figure-of-eight. Patients treated with a sling had higher treatment satisfaction than those treated with a figure-of-eight bandage.³ **SOR B**
- Midclavicular fractures can be treated with a clavicle brace; treat until radiographic evidence of healing has occurred. **SOR C** Wearing the brace frees the upper extremities for activities of daily living. The clavicle brace may improve the alignment of the midclavicular fracture.
- Refer patients with initial fracture shortening over 2 cm to discuss operative and conservative options. **SOR B** These patients have a higher risk of a nonunion associated with poor functional outcomes.⁴

Adult distal clavicular fractures

- Treat patients with nondisplaced distal clavicle fractures conservatively.
- Distal clavicle fractures are commonly treated by wearing a sling for 6 weeks to minimize the weight of the arm pulling on the distal clavicle fragment.
- Some patients with displaced distal clavicle fracture may benefit from surgery. Refer patients, other than the very elderly, to discuss risks and benefits of operative and nonoperative options.⁵

MEDICATIONS

- Treat pain as needed with acetaminophen or NSAIDs.

REFERRAL

- Refer for surgical evaluation, children with impingement of soft tissue/muscle, instability of shoulder girdle, displacement with skin perforation/necrosis, or risk to mediastinal structures.² **SOR C**
- Consider referring patients with displaced fractures. Nonoperative treatment has a 15.1% nonunion rate, whereas operative rates are 0% to 2%.¹
- Consider consulting with a physician skilled in managing clavicular fractures in patients with a distal clavicle fracture. These fractures have a high rate of nonunion; however, only a portion of nonunions are painful or inhibit function. If the patient continues to have a symptomatic nonunion after many months, surgery may be considered.

FIGURE 102-5 Acromioclavicular joint separation (third degree) with a wide AC joint and the clavicle displaced from the acromion. (From Simon RR, Sherman SC, Koenigskecht SJ. *Emergency Orthopedics the Extremities*. New York, NY: McGraw-Hill; 2007:297, Fig. 11-54. Copyright 2007.)

PROGNOSIS

- Midclavicular displaced fractures treated nonoperatively have a nonunion rate of up to 15% and a poor functional outcome in up to 5%. Operative nonunion rates are 0% to 2%.¹

- Patients with distal clavicle fractures treated nonoperatively had nonunion rates of 21%; however, there was no difference in function between those who healed and those with a nonunion.⁶ **SOR B**

FOLLOW-UP

- Monitor with examination and radiographs until pain has resolved, any lost function has returned, and there is radiographic evidence of healing. Initially, repeat x-ray every 1 to 2 weeks to evaluate for any change in alignment. If the fracture is stable, repeat x-ray every 4 to 6 weeks until the clavicle has healed. If there is no evidence of healing after 2 to 3 months, referral should be considered.

PATIENT EDUCATION

Most clavicle fractures heal without surgery, especially if the fracture is not displaced. Fractures in adults take 6 to 8 weeks to heal and fractures in children take approximately 3 to 4 weeks to heal. Often, there will be a bump at the site of the healed fracture, which typically does not interfere with any activities.

103 DISTAL RADIUS FRACTURE

Heidi Chumley, MD
Richard P. Usatine, MD

PATIENT STORY

A 65-year-old woman tripped on a rug in her home and fell on her outstretched hand with her wrist dorsiflexed (extended). She felt immediate pain in her wrist and has difficulty in moving her wrist or hand. She has been postmenopausal for 15 years and has never taken hormone replacement therapy or bisphosphates. She presented with pain and swelling in her wrist. Her arm had a “dinner-fork” deformity. Radiographs showed a distal radius fracture with dorsal angulation on the lateral view (**Figure 103-1**).

INTRODUCTION

Distal radius fractures are common, especially in postmenopausal women. Patients present with wrist pain and a “dinner-fork” deformity. Diagnosis is confirmed by radiographs. Treatment is either operative or nonoperative, based on the degree of displacement and the age of the patient.

SYNONYMS

Colles fracture is the most common type. Other types of distal radius fractures include Smith fracture, Barton fracture and Hutchinson fracture.

EPIDEMIOLOGY

- More common in older women—Female-to-male ratio of 3.2:1.¹
- Prevalence—In a community study of 452 people older than age 40 years in the United Kingdom, 10.8% of women and 2.6% of men had a prior distal radius fracture.²
- Incidence—In Sweden, the incidence is 115 per 100,000 women and 29 per 100,000 men.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- Classic history is a fall on an outstretched hand.
- In patients older than 40 years of age, there is a strong association with osteoporosis. Patients with low-impact distal radius fractures have higher rates of osteoporosis than age-matched controls without fractures by bone density measured at the wrist (60% vs. 35%; $p < 0.001$; odds ratio [OR], 5.7; 95% confidence interval [CI], 1.2 to 27.2) and lumbar spine (47% vs. 20%; $p < 0.005$; OR, 3.9; 95% CI, 1.1 to 14.3).³

FIGURE 103-1 Colles fracture. This occurred after a fall on an extended wrist. **A.** Lateral view shows a distal radius fracture with dorsal angulation. **B.** Anterior–posterior view demonstrating a transverse distal radius fracture. (Courtesy of Rebecca Loredó-Hernández, MD.)

- Postmenopausal women and older men with distal radius fractures have an increased risk for a future hip fracture (relative risk [RR] = 1.53; 95% CI, 1.34 to 1.74; $p < 0.001$; RR = 3.26; 95% CI, 2.08 to 5.11; $p < 0.001$, respectively).⁴

RISK FACTORS

Osteoporosis for men or women.⁵

DIAGNOSIS

Diagnosis is suspected by a compatible history, such as falling on a dorsiflexed wrist and confirmed with a plain radiograph showing the fracture of the distal radius (**Figure 103-1**).

CLINICAL FEATURES

Patients present with wrist pain and are not able to use the wrist or hand. The distal radius typically angles dorsally, creating the “dinner-fork” deformity (**Figure 103-1**). Swelling is usually present.

IMAGING

Wrist radiographs (two views) confirm the fracture and demonstrate the degree of displacement and angulation.

While Colles fracture is the most common distal radius fracture, there are 3 other types that can be classified based upon their radiographic appearance, history and physical exam:

1. Smith fracture is a reverse Colles fracture in which the angulation is in the palmar direction. It usually occurs after a fall on a flexed wrist or a direct blow to the dorsal wrist. The distal radial metaphysis it is displaced and angulated in the palmar direction and an associated ulna styloid fracture may be seen (**Figure 103-2**).
2. Barton fracture is an intraarticular dorsal or volar rim fracture. It occurs with forced wrist dorsiflexion and pronation. A triangular fragment of the distal radial styloid occurs as seen in **Figure 103-3**.
3. Hutchinson fracture (chauffeur’s fracture) is a fracture through the base of the radial styloid. It occurs with forced hyperextension of the wrist. There will be tenderness at the radial styloid on exam and the radiograph indicates a radial styloid fracture (**Figure 103-4**). It is also named a chauffeur’s fracture from the past when a chauffeur would crank a car manually and the kick back could break the wrist in this pattern.

DIFFERENTIAL DIAGNOSIS

Other causes of pain at the wrist include:

- Scaphoid fracture—Forced hyperextension, tenderness in anatomic snuffbox; radiograph demonstrates scaphoid fracture (70%).
- de Quervain tenosynovitis—No acute injury, pain on radial side of wrist from abductor pollicis longus and extensor pollicis brevis involvement, pain over the tendon when the thumb is placed into the patient’s fist and the wrist is deviated to the ulnar side; radiographs (not usually done) are normal.

FIGURE 103-2 Smith fracture (Reverse Colles fracture). A. Lateral view of a fracture of the distal radial metaphysis that is displaced and angulated in the palmar direction. This occurred after a fall on a flexed wrist. (Courtesy of Rebecca Loredó-Hernández, MD.)

FIGURE 103-3 Barton fracture. **A.** Lateral view showing a marginal fracture of the dorsal rim of the radius that is displaced along with the carpus producing a fracture-subluxation. **B.** AP view showing the triangular fragment of the radial styloid (arrow). (Courtesy of Rebecca Loredó-Hernandez, MD.)

FIGURE 103-4 Hutchinson fracture or chauffeur's fracture. This oblique view demonstrates a fracture through the base of the radial styloid (arrow). (Courtesy of Rebecca Loredó-Hernandez, MD.)

TABLE 103-1 Universal Classification of Radial Fractures

Fracture Classification	Management
I Nonarticular, nondisplaced	Immobilization with cast or splint ⁶ for 4 to 6 weeks
II Nonarticular, displaced	Reduction with cast or splint immobilization; surgical management if irreducible or unstable fracture
III Articular, nondisplaced	Immobilization; pinning if unstable
IV Articular, displaced	Surgical management (Figure 103-5 and Figure 103-6)

MANAGEMENT

Examine patients for the following associated complications:

- Flexor tendon injuries.
- Median and ulnar nerve injuries.

Examine radiographs for the following associated injuries:

- Ulnar styloid or neck fractures.
- Carpal fractures.
- Distal radioulnar subluxation.

Management is based on whether the fracture is nonarticular or articular, displaced or nondisplaced, reducible or irreducible (**Figure 103-5**). Although there are multiple accepted classification schemes, the Universal Classification of radial fractures, shown in **Table 103-1**, is the most straightforward when determining management.⁶ See **Figure 103-6** for a successful open reduction and internal fixation on a distal radial fracture. Note that this fracture was articular with displacement (**Figure 103-5**).

- The patient's wrist in most cases is splinted for the first few days after injury to allow swelling to decrease prior to casting.
- On the basis of the type of fracture, the patient's wrist is typically cast from 4 to 6 weeks and followed with serial radiographs.
- The patient should be referred to a musculoskeletal or orthopedic specialist if a fracture requires reduction. Management of displaced fractures is controversial, with surgical and nonsurgical treatments demonstrating similar outcomes.
 - External fixation, compared to cast immobilization, reduces displacement, but does not result in an improved functional outcome in adults.⁷
 - Open reduction and internal fixation was compared to closed reduction and cast fixation in patients older than age 65 years with an unstable displaced radial fracture. At 12 months, there was no difference in range of motion, pain, or function.⁸
- All patients with a low-impact distal radius fracture are at a higher risk for osteoporosis and clinicians should consider screening for osteoporosis.

PREVENTION

Screening for and treatment of osteoporosis may reduce fractures, including distal radial fractures.

FIGURE 103-5 31-year-old woman fell on a flexed wrist. **A.** Lateral view shows a distal radius comminuted intra-articular fracture with palmar displacement and volar angulation occurred (Smith fracture). This Type IV fracture is best managed with surgery. **B.** PA view shows an associated ulna styloid process fracture that is mildly displaced (arrow). (Courtesy of Richard P. Usatine, MD.)

PROGNOSIS

Most patients recover adequate function and do not have chronic pain, whether treated nonsurgically or surgically. In nonsurgically treated patients, higher degree of displacement leads to increased risk of poor function or pain 10 years after fracture.⁹

FOLLOW-UP

- Management and follow-up often involve a physician with expertise in managing distal radial fractures.
- Evaluate for osteoporosis.

PATIENT EDUCATION

- Distal radial fractures may result in limitations of wrist function.
- Nontraumatic fractures, in patients older than 40 years of age, may indicate osteoporosis.

PATIENT RESOURCES

- WebMD has information on distal radial fractures—<http://www.webmd.com/a-to-z-guides/colles-fracture>.

PROVIDER RESOURCES

- *Wheeless' Textbook of Orthopaedics* has additional information about the types of distal radius fractures, classification systems, and radiographic findings—<http://www.whelessonline.com/ortho/12591>.

104 METATARSAL FRACTURE

Heidi Chumley, MD

PATIENT STORY

A 37-year-old man inverted his ankle while playing basketball with his teenagers in their driveway. He felt a pop and had immediate pain. He had tenderness over the base of his fifth metatarsal. Having met the Ottawa ankle rules for radiographs (see later), a radiograph was obtained, which revealed a nondisplaced fracture at the base of the fifth metatarsal (**Figure 104-1**).

INTRODUCTION

Most metatarsal fractures involve the fifth metatarsal and include avulsion fractures at the base, acute diaphyseal fractures (Jones fracture), and diaphyseal stress fractures. Fractures of the first through fourth metatarsals are less common but can be associated with a Lisfranc injury. Diagnosis is based on the mechanism of injury or type of overuse activity and radiographic appearance. Treatment depends on the type of fracture. Most metatarsal fractures have a good prognosis; however, Jones fractures have a high rate of nonunion and Lisfranc injuries can result in chronic symptoms.

SYNONYMS

Avulsion fracture at base of fifth metatarsal: fifth metatarsal tuberosity fracture, dancer fracture, pseudo-Jones fracture.

Jones fracture: acute diaphyseal fracture of the fifth metatarsal.

EPIDEMIOLOGY

- Foot fractures are common injuries among recreational and serious athletes; however, incidence and prevalence in most populations is unknown.
- In women older than age 70 years, the incidence of foot fractures is 3.1 per 1000 woman-years, and more than 50% of these are fifth metatarsal fractures.¹
- Fifty percent of metatarsal fractures in adults ages 16 to 75 years involve the fifth metatarsal.²
- The majority of fifth metatarsal fractures are avulsion injuries (**Figure 104-1**).
- Twenty-three percent of elite military personnel sustain metatarsal stress fracture; most of these occur after 6 months of training.³

ETIOLOGY AND PATHOPHYSIOLOGY

- Avulsion fractures result when the peroneus brevis tendon and the lateral plantar fascia pull off the base of the fifth metatarsal, typically during an inversion injury while the foot is in plantar flexion.

FIGURE 104-1 Fifth metatarsal tuberosity avulsion fracture (dancer fracture). (From Simon RR, Sherman SC, Koenigskecht SJ. *Emergency Orthopedics, The Extremities*, 5th ed. New York: McGraw-Hill; 2007: 488, Fig. 18-21B. Copyright 2007.)

- Jones (acute diaphyseal) fracture results from landing on the outside of the foot with the foot plantar flexed.
- Diaphyseal stress fractures are caused by chronic stress from activities such as jumping and marching.
- Fractures of the first through fourth metatarsals are caused by direct blows or falling forward over a plantar-flexed foot. These fractures may be associated with a Lisfranc injury.

DIAGNOSIS

The diagnosis of avulsion or Jones fractures is made on plain radiographs in a patient with a history of injury and acute lateral foot pain. Diaphyseal stress fractures may require CT imaging.

CLINICAL FEATURES

- Avulsion injury—Sudden onset of pain (and tenderness on examination) at the base of the fifth metatarsal after forced inversion with the foot and ankle in plantar flexion.
- Acute Jones fracture—Sudden pain at the base of the fifth metatarsal, with difficulty bearing weight on the foot, after a laterally directed force on the forefoot during plantar flexion of the ankle.
- Stress fracture—History of chronic foot pain with repetitive motion.

IMAGING

- Avulsion fracture—Fracture line at base of fifth metatarsal oriented perpendicularly to the metatarsal shaft (**Figure 104-1**). May extend into joint with cuboid bone, but does not extend into the intermetatarsal joint.
- Acute Jones fractures (**Figure 104-2**) and stress fractures both have a fracture line through the proximal 1.5 cm of the fifth metatarsal shaft. These should be classified into type I, II, or III as below:⁴
 - Type I fractures have a sharp, narrow fracture line, no intramedullary sclerosis, and minimal cortical hypertrophy.
 - Type II fractures (delayed unions) have a widened fracture line with radiolucency, involve both cortices, and have intramedullary sclerosis.
 - Type III fractures (nonunions) have a wide fracture line, periosteal new bone and radiolucency, and obliteration of the medullary canal by sclerotic bone.
- Early stress fractures may have normal radiographs and can be seen on CT, MRI, or bone scan. Ultrasound may be a less expensive option—sensitivity 83%, specificity 76%, positive predictive value 59% and negative predictive value 92% in one small study.⁵

DIFFERENTIAL DIAGNOSIS

Pain at the fifth metatarsal can also be caused by:

- Diaphyseal stress fracture—May be radiographically similar to Jones fracture but is often seen more distally in the shaft; occurs in patients with no injury and history of overuse (e.g., ballet dancing, marching).

FIGURE 104-2 Jones fracture, a transverse fracture at the junction of the diaphysis and metaphysis. (From Simon RR, Sherman SC, Koenigsnecht SJ. *Emergency Orthopedics, The Extremities*, 5th ed. New York: McGraw-Hill; 2007:488, Fig. 18-21A. Copyright 2007.)

- Lisfranc injury—Disruption of the tarsal metatarsal joints. This pain is typically in the midfoot and more commonly medial. May be associated with fractures in the first through fourth metatarsals.

X-ray findings that can be confused with foot fractures include:

- Apophysis, a secondary center of ossification at the proximal end of the fifth metatarsal seen in girls, ages 9 to 11 years, and boys, ages 11 to 14 years. The apophysis is oblique to the metatarsal shaft, whereas avulsion fractures are perpendicular.
- Accessory ossicles (i.e., os peroneum, located at the lateral border of the cuboid) have smooth edges, whereas avulsion fractures have rough edges.

MANAGEMENT

Apply the Ottawa ankle rules to determine which patients with an injury and ankle/foot pain should have an X-ray.⁶ **SOR A** Ottawa rules: X-ray patients who cannot walk four steps immediately after the injury or who have localized tenderness at the posterior edge or tip of either malleolus, the navicular, or the base of the fifth metatarsal.⁶

- Treat nondisplaced avulsion fractures with an ankle splint or walking boot with ambulation for 3 to 6 weeks.⁷ **SOR B** Refer displaced avulsion fractures.
- Consider referring Jones fractures because of the high rate of nonunion caused by the poor blood supply. Type I or II may be treated with immobilization for at least 6 to 8 weeks. Type II can also be treated with surgery. Type III requires surgical repair. Elite athletes or patients needing a faster recovery are often surgically treated.⁸ **SOR B**
- Treat stress fractures with elimination of the causative activity for 4 to 8 weeks. Immobilization is often not required. If walking is painful, partial or non-weight bearing for 1 to 3 weeks may be necessary.⁹

Refer patients with:⁹

- Neurovascular compromise, compartment syndrome or open fractures.
- First metatarsal fracture, multiple metatarsal fractures, displaced fracture, intraarticular fracture, or Lisfranc injury.
- Inadequate response to treatment.

PROGNOSIS

Metatarsal fractures have an excellent outcome, with most patients symptom free at 33 months. Patients with higher body mass index (BMI), diabetes mellitus, women, and a dislocation with the fracture have less-positive outcomes.²

FOLLOW-UP

Patients should be followed every 1 to 3 weeks to evaluate for appropriate clinical and radiographic response to treatment.

PATIENT EDUCATION

Patients with nondisplaced avulsion fractures require a splint or boot, but can remain ambulatory. Jones fractures have a poor blood supply and often do not reconnect, even with immobilization. Surgery may result in a faster return to activities in some cases.

PATIENT RESOURCES

105 HIP FRACTURE

Heidi Chumley, MD

PATIENT STORY

A 60-year-old woman comes to the emergency room for hip pain. She felt a pop in her hip accompanied by the immediate onset of pain that prohibited her from walking. She had fallen 2 days prior. **Figure 105-1** shows a transcervical left femoral neck fracture with varus angulation and superior offset of the distal fracture fragment. She was evaluated by an orthopedic surgeon and underwent surgery the next day (**Figure 105-2**). After many months of rehabilitation, she was able to walk again.

EPIDEMIOLOGY

- Approximately 300,000 hip fractures per year occur in the United States.¹
- Seventy percent to 80% of hip fractures occur in women.¹
- Average age is 70 to 80 years; risk increases with age.¹
- Half of the patients with a hip fracture have osteoporosis.²

ETIOLOGY AND PATHOPHYSIOLOGY

- Approximately 95% of hip fractures are caused by a fall.

RISK FACTORS

- Low body mass index (BMI) and low physical activity in postmenopausal women.³
- Low physical activity.³

Long-term use of proton pump inhibitor (PPI) is associated with increased risk of any fracture, including hip fracture.⁴

DIAGNOSIS

CLINICAL FEATURES: HISTORY AND PHYSICAL

- In a population study, major risk factors for hip fracture include:
 - Low bone mineral density (3.6-fold [95% confidence interval (CI), 2.6 to 4.5] in women and 3.4-fold [95% CI, 2.5 to 4.6] in men for each standard deviation [SD] [0.12 g/cm²] reduction in bone mineral density).⁵
 - Postural instability and/or quadriceps weakness.
 - A history of falls.
 - Prior hip fracture.⁵
 - Other factors associated with increased risk include: dementia, tobacco use, physical inactivity, impaired vision, and alcohol use.

Physical examination—Abducted and externally rotated hip; limp or refusal to walk.

FIGURE 105-1 Transcervical left femoral neck fracture with varus angulation and superior offset of the distal fracture fragment. The femoral head is within the acetabular cup. Degenerative changes of the left hip are also present. (Courtesy of John E. Delzell, Jr., MD.)

TYPICAL DISTRIBUTION

- Hip fractures are classified according to anatomic location.⁶
 - Intracapsular (femoral neck fracture; **Figures 105-1** and **105-3**).
 - Extracapsular (intertrochanteric or subtrochanteric fracture; **Figure 105-4**).

IMAGING

- Radiographs—Plain radiographs show most hip fractures.
- Consider MRI, bone scan, or CT for indeterminate radiographs.

DIFFERENTIAL DIAGNOSIS

Hip pain can be caused by bone or joint pathology, soft-tissue injuries, spine pathology, or can be referred. Some causes include:⁶

- Pelvic fractures, bone cancers, or metastases; osteoarthritis, inflammatory, crystal, or septic arthritis.
- Iliotibial band syndrome, trochanteric bursitis, iliopsoas bursitis, piriformis syndrome, muscle strain.
- Lumbar disc herniation, lumbar spinal stenosis, sciatica.
- Hernia, abdominal or pelvic pathology.

MANAGEMENT

Preventing hip fracture is important; 50% of patients with a hip fracture do not regain previous level of function; 20% die within a year.

Lower risk of hip fracture by:

- Screening for osteoporosis.⁷ **SOR B**
- Treating osteoporosis with bisphosphonates. **SOR A**
- Preventing falls by monitoring vision; assessing gait, strength, and balance; and minimizing the use of psychotropic medications in the elderly. **SOR C**
- Encouraging exercise, such as tai chi, for lower-body strengthening and balance.
- Calcium and vitamin D supplementation do not decrease risk of hip fracture, but should be part of an osteoporosis prevention and treatment strategy.⁸ **SOR A**
- Providing hip protectors to older residents of nursing home facilities may reduce the number of hip fractures; however, the clinical significance of the intervention is unclear.⁹ **SOR A**

Refer to an orthopedic surgeon unless the patient is not healthy enough to withstand surgery.

PREVENTION

- Thiazide diuretics may reduce the risk of hip fracture by 24%, based on metaanalysis of observational studies.¹⁰
- Population interventions are effective. Kaiser Permanente decreased hip fractures by 40% by identifying patients who had not

FIGURE 105-2 Postsurgical portable radiograph demonstrating good positioning of artificial hip. (Courtesy of John E. Delzell, Jr., MD.)

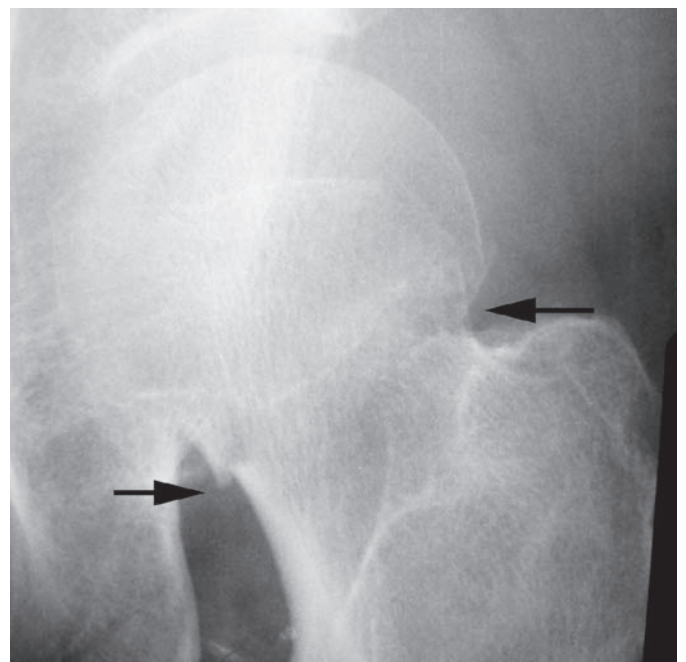

FIGURE 105-3 Nondisplaced, complete, femoral neck fracture (black arrows). Nondisplaced fractures can be incomplete (fracture through part of the femoral neck) or complete (fracture through the entire femoral neck). (From Simon RR, Sherman SC, Koenigsnecht SJ. *Emergency Orthopedics, The Extremities*, 5th ed. New York: McGraw-Hill; 2007:358, Fig. 13-8. Copyright 2007.)

received recommended bone density screening and treating as appropriate.¹¹

PROGNOSIS

- One-year postoperation mortality of 27.3%.¹²
- All-cause mortality is three times higher in patients with a hip fracture than in the general population.¹²

FOLLOW-UP

Patients with hip fracture may benefit from multidisciplinary follow-up, including monitoring for complications such as avascular necrosis, identifying and treating osteoporosis, modifying risk factors for further falls, and maximizing function through therapy.

PATIENT EDUCATION

It is much easier to prevent hip fractures than to treat hip fractures. After a hip fracture, patients often need prolonged time (months) in a nursing care facility. Physical therapy is crucial in regaining as much function as possible.

106 THE KNEE

Heidi Chumley, MD

PATIENT STORY

A 33-year-old woman felt a pop in her knee while skiing around a tree. She felt immediate pain and had difficulty walking when paramedics removed her from the slopes. Within a couple of hours, her knee was swollen. On examination the next day, she was able to walk 4 steps with pain. She had a moderate effusion without gross deformity and full range of motion. She had no tenderness at the joint line, the head of the fibula, over the patella, or over the medial or lateral collateral ligaments. She had a positive Lachman test, a negative McMurray test, and no increased laxity with valgus or varus stress. The physician suspected an anterior cruciate ligament (ACL) tear, placed her in a long leg range of motion brace, and advised her to use crutches until an evaluation by her physician within the next several days. She was treated with acetaminophen for pain and advised to rest, apply ice, and keep her leg elevated. Later, an MRI confirmed an ACL tear (**Figure 106-1**).

INTRODUCTION

Knee injuries are common, especially in adolescents. Women have a greater risk of knee injuries because of body mechanics. Most knee injuries involve the ACL, meniscus, or medial or lateral collateral ligaments. The mechanism of injury and physical examination findings suggest the type of injury, which can be confirmed by MRI. Treatment includes rest, ice, compression, elevation, and referral to an orthopedic surgeon.

EPIDEMIOLOGY

- Knee injuries are the second most common adolescent sporting injury (after ankle injuries)¹ and typically are seen in sports requiring pivoting, such as basketball or football. **Figure 106-2** shows the normal anatomy of the knee.
- The risk of ACL injury while playing soccer, is 2 to 3 times higher in females than in males after the age of 12 years.²
- The risk of ACL injury was 3.79 times greater in girls in a prospective study of boy and girl high school basketball players in Texas.¹
- Incidence of ACL injuries was approximately 3 per 1000 person-years in United States active military personnel, with no difference in gender.³
- Meniscal injuries commonly occur with ACL tears (23% to 65%).⁴
- Meniscal tears were seen on MRI in 91% of patients with symptomatic osteoarthritis, but also seen in 76% of age-matched controls without knee pain.⁵
- Collateral ligament injuries account for approximately 25% of acute knee injuries.

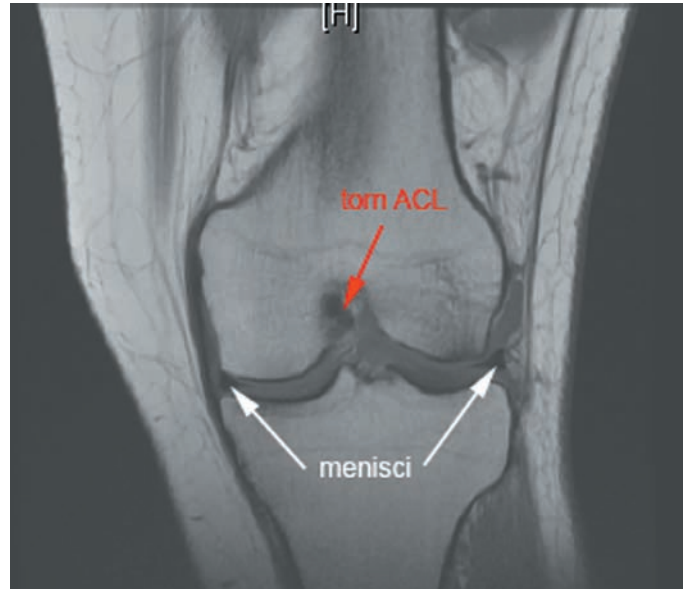

FIGURE 106-1 MRI of ACL tear in the frontal view. Note the normal menisci, which are black throughout. (Courtesy of John E. Delzell, Jr., MD, MSPH.)

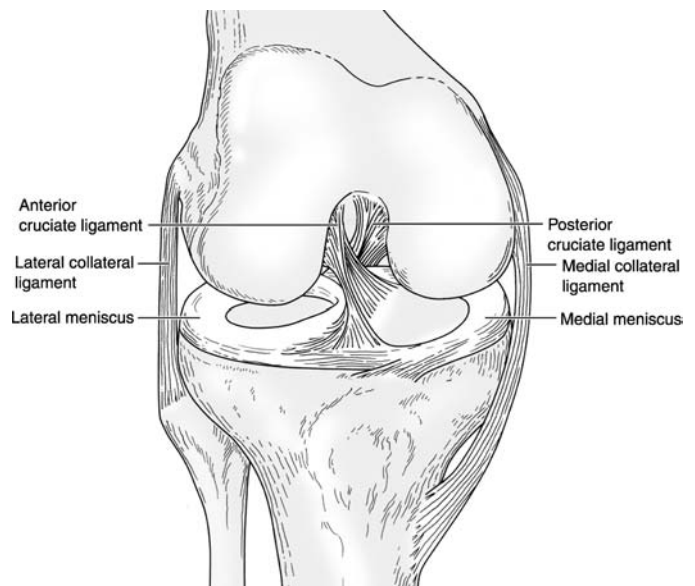

FIGURE 106-2 Anatomy of a normal knee. (From Simon RR, Sherman SC, Koenigsnecht SJ. *Emergency Orthopedics, The Extremities*, 5th ed. New York, NY: McGraw-Hill; 2007:392, Fig. 15-5. Copyright 2007.)

ETIOLOGY AND PATHOPHYSIOLOGY

- ACL injuries occur with sudden deceleration with a rotational maneuver, usually without contact.
- ACL injuries are thought to occur more commonly in women because of decreased leg strength, increased ligamentous laxity, and differences in lumbopelvic core control.
- Acute meniscal injuries occur with a twisting motion on the weight-bearing knee.
- Chronic meniscal tears occur from mechanical grinding of osteophytes on the meniscus in older patients with osteoarthritis.
- Medial collateral and lateral collateral injuries occur from valgus and varus stress, respectively.

RISK FACTORS

Women are at higher risk for ACL injuries.

DIAGNOSIS

CLINICAL FEATURES ON HISTORY

ACL:

- Rotational injury.
- “Pop” reported by patient.
- Unable to bear full weight.
- Effusion within the first few hours.

Meniscal injury:

- Foot planted with femur rotated internally with valgus stress (medial) or femur rotated externally with varus stress (lateral).
- Joint line pain.
- Effusion over the first several hours.
- Usually ambulatory with instability or locking (mechanical) symptoms.

Collateral injury:

- Valgus or varus stress injury.
- Usually ambulatory without instability or locking symptoms.

PHYSICAL EXAMINATION

A complete physical exam of the knee is demonstrated online from the University of British Columbia at <http://www.youtube.com/user/BJSMVideos>.

- Inspect the knee for effusions—Usually present for an ACL tear.
- Test range of motion—Often normal; inability to extend fully can indicate either a medial meniscal tear or an ACL tear displaced posteriorly.
- Palpate for tenderness—Joint line tenderness may indicate a meniscal tear (likelihood ratio, LR+ = 1.1; LR− = 0.8).⁶ Tenderness at the head of the fibula or at the patella are 2 of the 5 Ottawa

rules for obtaining radiographs; tenderness along the medial or lateral collateral ligament may indicate damage to those ligaments.

- Perform tests for ACL tear—Lachman test (LR+ = 12.4; LR- = 0.14),⁶ anterior drawer test (LR+ = 3.7; LR- = 0.6),⁶ pivot shift test (LR+ = 20.3; LR- = 0.4).⁶
- Patients with ACL tears typically have a history of rotational injury; inability to bear weight; positive provocative tests; normal plain radiographs; and abnormal MRI.
- Perform tests for meniscal tears—McMurray test (LR+ = 17.3; LR- = 0.5).⁶
- Patients with meniscal tears typically have history of rotational injury with valgus/varus stress or history of osteoarthritis; able to bear weight, commonly with instability or locking; positive McMurray test; normal plain radiographs; and abnormal MRI.
- Perform varus and valgus stress to test the lateral and medial collateral ligaments.
- Patients with injuries to the collateral ligaments typically have a history of valgus/varus stress to extended knee; able to bear weight without instability or locking; laxity with valgus or varus stress testing; normal plain radiographs and abnormal MRI.

IMAGING

- Determine whether or not to obtain plain radiographs (anteroposterior, lateral, intercondylar notch, and sunrise views) to assess for a fracture based on either the Pittsburgh or Ottawa knee rules (the Ottawa rules may be less sensitive in children):
 - Pittsburgh (99% sensitivity, 60% specificity; tested in population ages 6 to 96 years)⁶—Obtain x-ray for:
 - Recent significant fall or blunt trauma.
 - Age younger than 12 years or older than 50 years.
 - Unable to take 4 unaided steps.
 - Ottawa (98.5% sensitivity, 48.6% specificity; LR- = 0.05; tested in 6 studies of 4249 adult patients)⁷—Obtain x-ray for:
 - Age 55 years or older.
 - Tenderness at the head of the fibula.
 - Isolated tenderness of the patella.
 - Inability to flex knee to 90 degrees.
 - Inability to bear weight for 4 steps both immediately and in the examination room regardless of limping.
- MRI is 95% and 90% accurate in identifying ACL tears and meniscal injuries, respectively (Figures 106-2 to 106-4).⁸

DIFFERENTIAL DIAGNOSIS

Acute knee pain can be caused by trauma affecting structures of the knee other than ligaments and menisci, arthritis, infection, or tumors including:

- Trauma.
- Intraarticular fractures (patella, femoral condyles, tibial eminence, tibial tuberosity, and tibial plateau)—history of trauma or chronic overuse; edema, ecchymosis, point tenderness, or deformity may be present; visible on plain radiographs (Figures 106-5 and 106-6).

FIGURE 106-3 Medial meniscal tear on the frontal view, seen as a small white line through the black meniscus. (Courtesy of Heidi Chumley, MD.)

FIGURE 106-4 Lateral meniscal tear on a sagittal view, seen as a small white line in the black meniscus. (Courtesy of Heidi Chumley, MD.)

- Patellar dislocation—Severe hyperextension (anterior dislocation), fall on a bent knee or knee hitting the dashboard (posterior dislocation), valgus or varus stress (medial or lateral dislocation); visible deformity; effusion and immobility; neurovascular complications (peroneal nerve and popliteal artery); visible on plain radiographs.
- Arthritis—No history of trauma.
- Reactive arthritis—Fever/malaise; oligoarthritis involving the knee, ankle, feet and/or wrist involvement, urethritis, conjunctivitis or iritis; elevated C-reactive protein or erythrocyte sedimentation rate (ESR); arthritic changes on radiographs (see Chapter 155, Reactive Arthritis).
- Juvenile rheumatoid arthritis (JRA)—Children younger than age 16 years; acute pain and swelling without trauma; fever or skin rashes (systemic JRA); knee is commonly involved; arthritic changes on plain radiographs.
- Rheumatoid arthritis—Adults ages 30 to 50 years, more commonly women; polyarthritis involving hands, wrists, feet, and knees; fever/malaise; positive rheumatoid factor; erosive arthritis changes on radiographs (see Chapter 97, Rheumatoid Arthritis).
- Gout or pseudogout—Adults ages 30 to 60 years, more commonly men; single joint erythema, warmth and tenderness without trauma; abnormal joint fluid with elevated white blood cell count (WBC); radiographs may be normal or abnormal (sclerotic regions, degenerative changes, or soft tissue calcifications) (see Chapter 100, Gout).
- Osteoarthritis—Older adults; gradual onset; symptoms worse after use; radiographic osteophytes (see Chapter 96, Osteoarthritis).
- Infections such as cellulitis, septic arthritis (**Figure 106-7**), osteomyelitis—May have history of skin break by bite or puncture wound; fever; erythema, warmth with cellulitis; decreased range of motion, inability to walk, abnormal fluid aspirate with septic arthritis; chronic symptoms and abnormal radiograph with osteomyelitis.
- Malignant tumors (e.g., osteosarcoma, chondroblastoma) or benign tumors (e.g., bone cysts, osteochondroma)—No (or insignificant) history of trauma; chronic symptoms or acute symptoms caused by pathologic fracture; abnormal radiographs and MRI.

MANAGEMENT

Initial management for traumatic knee pain includes rest, ice, compression, and elevation.

- Provide pain relief with acetaminophen. Add a nonsteroidal antiinflammatory medication if needed.⁹ **SOR C**
- Prevent further injury (e.g., limit activities to toe-touch weight bearing and place in a long leg range of motion brace)⁸ until evaluation by a provider trained to manage acute knee injuries. **SOR C**
- Obtain plain radiographs if indicated by the Pittsburgh or Ottawa rules.⁷ **SOR A**
- Consider an MRI for suspected ACL, meniscal, or collateral ligament tear based on the mechanism of injury and physical examination findings.⁸ **SOR C**

FIGURE 106-5 Nondisplaced patellar fracture seen best on the lateral view. (From Simon RR, Sherman SC, Koenigsknecht SJ. *Emergency Orthopedics, The Extremities*, 5th ed. New York, NY: McGraw-Hill; 2007:405, Fig. 15-26, bottom photo only. Copyright 2007.)

FIGURE 106-6 Lateral condylar split fracture (type 1) has no depression of the articular surface and is usually the result of low-impact trauma. More common in children. (From Simon RR, Sherman SC, Koenigsknecht SJ. *Emergency Orthopedics, The Extremities*, 5th ed. New York, NY: McGraw-Hill; 2007:398, Fig. 15-14. Copyright 2007.)

FOR ACL TEARS

- Refer to a physician trained in surgical repair as repair results in 80% to 95% return to normal activity in 4 to 6 months.⁹ **SOR C**
- Surgical repair is typically done at least 3 weeks after the injury. Repair within the first 3 weeks results in a high incidence of arthrofibrosis.
- Refer to physical therapy if available to institute early knee range of motion (before surgery).⁹ **SOR C**

FOR MENISCAL TEARS

- Refer to a physician for discussion of nonsurgical and surgical treatments as rates of healing vary by location of meniscal tear and associated injuries.¹⁰ **SOR C**

FOR COLLATERAL TEARS

- The treatment is based on the severity of the tear. **SOR C**
- For all grades, instruct in early range of motion exercises (or refer to physical therapy).
- Grade I medial collateral ligament (MCL) or lateral collateral ligament (LCL) (≤ 5 cm laxity on valgus or varus stress), weight-bearing as tolerated with early ambulation.
- Grade II MCL or LCL (5 to 10 cm laxity), place in a brace blocking the last 20 degrees of flexion, weight-bearing as tolerated.
- Grade III MCL (>10 cm laxity), place in a hinged brace, initially non-weight bearing, advancing to weight bearing over 4 weeks. Grade III LCL tears often require surgery.

PREVENTION

- Neuromuscular retraining programs reduce the incidence of ACL injuries in female basketball, soccer, and basketball players.¹¹
- The Prevent Injury, Enhance Performance Program achieved a 75% to 88% reduction in ACL injuries among female soccer players ages 14 to 18 years. The program includes warm-up, stretching, strengthening, plyometrics, and agility exercises.¹²
- Structured warm-up program to improve cutting, jumping, balance and strength decreased acute knee injuries, number needed to treat was 43 over 8 months.¹³

PROGNOSIS

Of children and adolescents who have had ACL surgery, 84.2% achieve excellent or good knee function.¹⁴

Nonsurgical management of ACL tears have a good prognosis from 1 to 5 years, but patients reduce their activity level by 21%.¹⁵

FOLLOW-UP

Timing of follow-up is determined by the orthopedic surgeon, sports medicine specialist, or other provider skilled in acute knee injury management.

FIGURE 106-7 Septic arthritis in a young girl who presented with a painful swollen left knee, decreased range of motion and difficulty walking. A knee aspiration revealed turbid fluid with elevated leukocytes. The joint fluid culture grew *Staphylococcus aureus*. (Courtesy of Richard P. Usatine, MD.)

PATIENT EDUCATION

- ACL tears often require surgery, take 4 to 6 months to heal, and require a commitment to rehabilitation for the best results.
- Meniscal tears may require surgery when mechanical symptoms are present. The location of the tear determines how likely surgical repair is to be effective because of the blood supply available for healing.
- Meniscal tears are commonly seen on MRI in patients with osteoarthritis who do not have pain and meniscal tears seen on MRI may not be contributing to arthritic pain.
- Collateral tears can often be treated conservatively, while protecting the knee in a brace and preserving range of motion. Complete tears to the LCL often require surgery.

PATIENT RESOURCES

107 DUPUYTREN DISEASE

John E. Delzell, Jr., MD, MSPH
Heidi Chumley, MD

PATIENT STORY

A 53-year-old man presented with stiffness in his hands. He said his hands began to feel stiff several years ago, and now he finds that he cannot straighten many of his fingers (**Figure 107-1**). He delayed seeing a physician because he did not feel any pain in his hands. He recently began having difficulty holding his woodworking tools and wants to regain the function he has lost in his hands. The physician diagnosed him with Dupuytren contracture and discussed the disease with him along with his options for treatment.

INTRODUCTION

Dupuytren contracture is a flexion contracture of one or more of the fingers in the hand. Patients develop a progressive thickening of the palmar fascia, which causes the fingers to bend in toward the palm and limits extension. Diagnosis is clinical and the palpable nodules in the palm are considered diagnostic. Treatment has historically been surgical, but a new nonsurgical treatment with a collagenase has been approved.

SYNONYMS

Dupuytren disease, Dupuytren contractures, palmar fibromatosis, morbus Dupuytren, Ledderhose disease.

EPIDEMIOLOGY

- Dupuytren contracture is an autosomal dominant disease with incomplete penetrance (**Figure 107-2**).
- Higher prevalence among whites, particularly of Northern European descent. There is an increasing incidence related to aging.⁵
- More common in men than women (approximately 6:1).^{1,3}
- Incidence in the United States is estimated to be approximately 3 per 10,000 adults with an estimated prevalence of 7%.
- Higher incidence in people who use tobacco and alcohol or who have diabetes mellitus or epilepsy.²

ETIOLOGY AND PATHOPHYSIOLOGY

Dupuytren contractures form in three stages:

- Myofibroblasts in the palmar fascia proliferate to form nodules.
- Myofibroblasts then align along the lines of tension, forming cords.
- Tissue becomes acellular leaving thick cords of collagen that tighten resulting in flexion contractures at the metacarpal phalangeal joint,

FIGURE 107-1 Dupuytren contracture in a 53-year-old man showing flexion contractures at the proximal interphalangeal joints of the third digit and a palmar cord. (Courtesy of Richard P. Usatine, MD.)

FIGURE 107-2 Dupuytren contracture in a 60-year-old man showing a flexion contracture of the fifth digit and a palmar cord. All of his brothers have Dupuytren contractures. (Courtesy of Richard P. Usatine, MD.)

the proximal interphalangeal joint, and, occasionally, the distal interphalangeal joint.

RISK FACTORS

- Tobacco use.
- Alcohol consumption.
- Epilepsy.
- Diabetes mellitus.
- Carpal tunnel syndrome.
- History of manual labor.
- History of hand injury.

DIAGNOSIS

CLINICAL FEATURES

- Clinical diagnosis that is based on the history and physical examination.
- Patients complain of a slowly progressive tightness in the hands and a lack of the ability to fully extend their fingers.
- Typically painless.
- Examination findings—Nodules with flexion contractures are considered diagnostic, particularly in older white males; however, nodules may disappear late in the disease.²

TYPICAL DISTRIBUTION

- Can be either hand.
- More commonly seen in the fourth and fifth digits (**Figure 107-3**).

LABORATORY TESTING

- Not indicated.

IMAGING

- MRI of the contractures may be helpful prior to surgical intervention, but is not needed to confirm a clinical diagnosis.

BIOPSY

- Typically not indicated.
- Early diagnosis or diagnosis in atypical populations, such as children, may require histologic confirmation.

DIFFERENTIAL DIAGNOSIS

Consider the other causes of hand contractures and palmar nodules including:

- Intrinsic joint contractures—Loss of range of motion from any primary joint disease.
- Trigger finger, stenosing tenosynovitis—Localized swelling of the flexor tendon limits movement within the sheath with resulting “triggering”; digit catches, but can be straightened.

FIGURE 107-3 Dupuytren contracture in a 58-year-old man showing flexion contractures of the fourth and fifth digits and a palmar cord. (Courtesy of Richard P. Usatine, MD.)

- Rheumatoid arthritis—Bony deformities resulting in ulnar deviation at the metacarpophalangeal joints and/or the wrist.
- Ganglion cysts and palmar nodules.
- Occupational hyperkeratosis and callous formation.
- Hand tumors including epithelioid sarcomas and soft-tissue giant cell tumors.

MANAGEMENT

The treatment goal of Dupuytren contracture is to maintain or restore hand function by increasing range of motion at involved joints.

NONPHARMACOLOGIC

- Physical therapy with splinting does not seem to be helpful as a sole treatment. **SOR C**
- Radiation therapy has been used but there is little evidence to support it and significant potential side effects of the treatment. **SOR C**
- Hyperbaric oxygen is being studied with mixed results. **SOR C**

MEDICATIONS

- Intralesional injection of corticosteroids is only mildly successful and may place the patient at risk for tendon rupture. **SOR C**
- Collagenase injection, a nonsurgical treatment, shows promise in phase II and phase III trials.⁴ **SOR B**

REFERRAL FOR SURGERY

- Surgical correction is considered when there is at least 30 degrees of contracture at the metacarpophalangeal (MCP) joint. **SOR C**
- Surgical fasciotomy decreases the degree of flexion deformity and results in modest improvements in hand function. Studies indicated that improvements in function are best correlated to changes at the proximal interphalangeal joint.⁵ **SOR B**

PROGNOSIS

- Recurrence rate is related to the amount of fascia that is removed on surgery.
- There is an increased risk for recurrence with time.

FOLLOW-UP

- Postoperative follow-up should include hand therapy with a goal of increasing extension in the affected digits.

PATIENT EDUCATION

- Modifying risk factors (e.g., smoking, alcohol intake) known to contribute to the development of Dupuytren contracture is prudent, but are not shown to alter the course of the disease.

- After surgery, postoperative hand therapy may improve function and use of the hand. However, initial decreases in joint deformity and improvements in hand function may be lost over time.

DERMATOLOGY

Strength of Recommendation (SOR)	Definition
A	Recommendation based on consistent and good-quality patient-oriented evidence.*
B	Recommendation based on inconsistent or limited-quality patient-oriented evidence.*
C	Recommendation based on consensus, usual practice, opinion, disease-oriented evidence, or case series for studies of diagnosis, treatment, prevention, or screening.*

*See Appendix A on pages 1447–1450 for further information.

SECTION 1 CHILDHOOD DERMATOLOGY

108 NORMAL SKIN
CHANGES

Cristina Fernandez, MD
Mindy Smith, MD, MS

PATIENT STORY

A 2-week-old infant is brought to the office for her first well-baby check. The parents noticed a rash on the face. You diagnose the white spots on the bridge of the nose as milia and neonatal acne on the cheeks. The parents are happy to hear that the neonatal acne and milia will go away without treatment (**Figures 108-1** and **108-2**).

INTRODUCTION

- Rashes are common in newborns. Physicians will be consulted frequently as they are a common parental concern. Almost all newborn rashes are benign; however, a few are associated with more serious conditions. A newborn's skin shows a variety of changes during the first 2 months of life and most are self-limited. Physicians must be prepared to identify common rashes and advise parents.¹
- Milia are inclusion cysts that appear as tiny white papules in the skin (**Figure 108-1**) or on the roof of the mouth.
- Neonatal acne is an acneiform eruption appearing as small red papules or whiteheads with surrounding erythema on the skin of newborns (**Figure 108-2**).
- A mongolian spot is a hereditary, congenital macule of bluish-black or bluish-gray pigment usually in the sacral area, back, and buttocks of infants (**Figures 108-3** and **108-4**).
- Erythema toxicum neonatorum (ETN) is a benign, self-limited skin eruption appearing as small yellow-white papules or vesicles with surrounding skin erythema (**Figures 108-5** and **108-6**).

SYNONYMS

- Milia are also called milk spots or oil seed.
- Neonatal acne is also called acne neonatorum.
- Mongolian spots are also known as mongolian blue spots, congenital dermal melanocytosis, and dermal melanocytosis.

EPIDEMIOLOGY

- Approximately 40% of newborn infants in the United States develop milia.² This condition is mainly associated with newborns carried to full term or near term.

FIGURE 108-1 Milia on the face of a 2-week-old infant with greatest number of milia on the nose. (Courtesy of Richard P. Usatine, MD.)

FIGURE 108-2 Neonatal acne on the same infant. (Courtesy of Richard P. Usatine, MD.)

- Neonatal acne occurs in up to 20% of the newborns. It typically consists of close comedones of the forehead, nose, and cheeks, although other locations are possible. It is most frequent in boys in the first week of life.³
- The prevalence of mongolian spots varies among different ethnic groups. They have been reported in approximately 96% of black infants, 90% of Native American infants, 81% to 90% of Asian infants, 46% to 70% of Hispanic infants, and 1% to 10% of white infants.^{2,4,5}
- ETN occurs in 30% to 70% of full-term infants and in 5% of premature infants. The incidence rises with increasing gestational age and birth weight.^{6,7}

ETIOLOGY AND PATHOPHYSIOLOGY

- Milia are inclusion cysts that contain trapped keratinized stratum corneum surrounded by a dense lymphocytic infiltrate. Milia are caused by retention of keratin within the dermis. They may rarely be associated with other abnormalities in syndromes such as epidermolysis bullosa and the orofacial digital syndrome (type 1).^{2,8}
- Maternal androgenic hormones that stimulate sebaceous glands likely cause neonatal acne.⁹
 - Hyperactivity of sebaceous glands, stimulated by neonatal androgens, has been implicated as the underlying pathogenic mechanism.
 - Histologic examination shows hyperplastic sebaceous glands with keratin-plugged orifices.
- The mongolian spot is a hereditary, congenital, developmental condition exclusively involving the skin. It results from entrapment of melanocytes in the dermis during their migration from the neural crest into the epidermis.
 - Mongolian spots are associated with cleft lip, spinal meningeal tumor, melanoma, and phakomatosis pigmentovascularis types 2 and 5.^{2,10}
 - A few cases of extensive mongolian spots have been reported with inborn errors of metabolism, the most common being Hurler syndrome, followed by gangliosidosis type 1, Niemann-Pick disease, Hunter syndrome, and mannosidosis. In such cases, they are likely to persist rather than resolve.^{2,4}
- The etiology of ETN is not known. ETN is thought to be an immune system reaction; the condition is associated with increased levels of immunologic and inflammatory mediators (e.g., interleukins 1 and 8, eotaxin).¹¹
 - The eosinophilic infiltrate of ETN suggests an allergic-related or hypersensitivity-related etiology, but no allergens have been identified. Newborn skin appears to respond to any injury with an eosinophilic infiltrate.
 - Because ETN rarely is seen in premature infants, it is believed that mature newborn skin is required to produce this reaction pattern.

DIAGNOSIS

CLINICAL FEATURES

- Milia are characterized as tiny, pearly white papules (see **Figure 108-1**) that are actually small inclusion cysts ranging from 1 to 2 mm in diameter. No visible opening is present.²

FIGURE 108-3 Large mongolian spots covering the buttocks and back of a Hispanic infant. (Courtesy of Richard P. Usatine, MD.)

FIGURE 108-4 Prominent mongolian spots on the back of a 1-year-old black child. (Courtesy of Richard P. Usatine, MD.)

- Milia usually appear after 4 to 5 days of life in full-term newborns. Manifestations of milia may be delayed from days to weeks in infants born before term.^{8,10}
- Neonatal acne (**Figure 108-2**) includes comedones (i.e., whiteheads), papules, and pustules.
 - Papules and pustules are the most frequent types of lesions (72.7%), followed by comedones only (22.7%).^{2,9}
- A mongolian spot (**Figures 108-3** and **108-4**) is a bluish-black macule or patch typically a few centimeters in diameter, although much larger lesions also can occur. Lesions may be solitary or numerous.
 - Generalized mongolian spots involving large areas covering the entire posterior or anterior trunk and the extremities have been reported.
 - Several variants exist including:^{2,4}
 - Persistent mongolian spots—These are larger, have sharper margins, and persist for many years (**Figure 108-4**).
 - Aberrant mongolian spots involve unusual sites such as the face or extremities.
 - Persistent aberrant mongolian spots also are referred to as macular-type blue nevi.
- ETN commonly presents with a blotchy, evanescent, macular erythema (**Figures 108-5** and **108-6**).
 - The macules are irregular, blanchable, and vary in size.
 - In more severe cases (**Figure 108-6**), pale yellow or white wheals or papules on an erythematous base may follow. In approximately 10% of patients, 2- to 4-mm pustules develop.^{2,7}
 - ETN occurs within the first 4 days of life in full-term infants, with the peak onset within the first 48 hours following birth. Rare cases have been reported at birth.
 - Delayed onset can rarely occur in full-term and preterm infants up to 14 days of age.
 - Infants with ETN otherwise are healthy and lack systemic symptoms.

TYPICAL DISTRIBUTION

- Milia are found on the forehead, nose, upper lip, cheeks, and scalp. They can, however, occur anywhere and may be present at birth or appear subsequently. The milia on the child in **Figure 108-1** were present at birth.
- Neonatal acne occurs on the face with the cheeks being the most common site (81.8%) (**Figure 108-2**).²
- Mongolian spots most commonly involve the lumbosacral area (**Figure 108-3**), but the buttocks, flanks, and shoulders (**Figure 108-4**) may be affected with extensive lesions.
- ETN sites of predilection include the forehead, face, trunk, and proximal extremities, but lesions may occur anywhere, including the genitalia. Involvement of the mucous membranes and palms and soles rarely occurs (**Figures 108-5** and **108-6**).

LABS AND IMAGING

- No laboratory studies are required.
- In extensive mongolian spots involving the back, radiographic studies are needed to rule out a spinal meningeal tumor or anomaly.⁴

FIGURE 108-5 One small spot of ETN on a 2-day-old infant. (Courtesy of Richard P. Usatine, MD.)

FIGURE 108-6 More widespread case of ETN covering the infant. ETN is completely benign and will resolve spontaneously. (Courtesy of the University of Texas Health Sciences Center, Division of Dermatology.)

- ETN is often diagnosed clinically, based on history and physical examination, but a peripheral smear of intralesional contents can be done to confirm the diagnosis.^{2,7}
 - A Tzanck smear or Gram stain shows inflammatory cells with greater than 90% eosinophils and variable numbers of neutrophils.
 - A complete blood count (CBC) also shows eosinophilia (up to 18%) in approximately 15% of patients. Eosinophilia may be more pronounced when the eruption shows a marked pustular component.

DIFFERENTIAL DIAGNOSIS

Other diagnoses that may be confused with milia, neonatal acne, and ETN include:

- Miliaria—Heat rash (prickly heat) with tiny papules that can be red (miliaria rubra) or clear (miliaria crystallina) or pustular (miliaria pustulosa) (**Figure 108-7**). Miliaria results from sweat retention caused by partial closure of eccrine structures. Both milia and miliaria result from immaturity of the skin structures, but they are clinically distinct entities.
- Neonatal pustular melanosis—This eruption, present at birth, consists of 2- to 4-mm nonerythematous vesicles filled with a milky fluid. This rash occurs in 5% of African American newborns and in less than 1% of white newborns, and fades in the first 3 to 4 weeks of life (see Chapter 110, Pustular Diseases of Childhood).

Mongolian spots may be confused with the following lesions also present at birth or shortly after:

- Congenital melanocytic nevi—These lesions are much less common (1% to 2% of newborns). They are of variable color from tan or brown to red or black, often within a single lesion and the pigment may fade off into surrounding skin. The borders are often irregular and the lesion can appear slightly raised over time (although a macular portion is usually found at the edges). Most congenital melanocytic nevi have a darker color and more discrete borders than mongolian spots. A biopsy is only needed if melanoma is suspected (see Chapter 163, Congenital Nevi).
- There are reports of Mongolian spots being confused for the bruising that occurs in child abuse. A good history and a clear knowledge of the pattern of mongolian spots should help to differentiate between these two entities.

ETN can also be confused with the following:

- Miliaria—See information above.
- Folliculitis—Primary lesion is a papule or pustule pierced by a central hair, although the hair may not always be visualized. Deeper lesions present as erythematous, often fluctuant, nodules. Folliculitis rarely occurs in the first few days of life when ETN is most commonly seen (see Chapter 117, Folliculitis).
- Chickenpox—The characteristic rash appears in crops of lesions beginning with red macules and passing through stages of papule, vesicle (on an erythematous base), pustule, and crust. Simultaneous presence of different stages of the rash is a hallmark. Infants are mostly born with adequate maternal antibodies to varicella, so that timing should differentiate between these two conditions (see Chapter 123, Chickenpox).

FIGURE 108-7 Miliaria (heat rash) in a 6-month-old infant on a warm summer day. (Courtesy of Richard P. Usatine, MD.)

- Cutis marmorata (**Figure 108-8**) is reticulated mottled skin with symmetric involvement of the trunk and extremities produced by a vascular response to cold; the change resolves with heat. This entity can persist for weeks or months. No treatment is indicated.
- Harlequin color change affects 10% of full-term babies and occurs when the newborn lies on one side and erythema develops on one side of the body, while blanching is seen on the contralateral side. The color change fades after 30 seconds to 20 minutes and resolves with increased muscle activity or crying. It begins between the second to fifth days of life and lasts up to 3 weeks.¹²
- Neonatal lupus is a rare syndrome in which maternal autoantibodies are passively transferred to the baby producing well-demarcated, erythematous, scaling patches that are often annular, predominately on the scalp, neck or face (**Figure 108-9**). The condition is self-limited and resolves without scarring by 6 to 7 months of age. It is associated with congenital heart block. Treatment includes photoprotection; mild topical steroids may be helpful.

MANAGEMENT

- Milia, neonatal acne, mongolian spots, and ETN are benign conditions and parents should be reassured that they resolve with time.
- Although acne treatment generally is not indicated, infants can be treated with a 2.5% benzoyl peroxide lotion if lesions are extensive and persist for several months.⁹

PROGNOSIS

- Milia usually disappear within several weeks.
- Neonatal acne may come and go until the baby is between 4 and 6 months of age.
- Mongolian spots may persist for many years but usually disappear within 3 to 5 years and almost always by puberty.
- ETN usually lasts for several days but can change rapidly, with lesions appearing and disappearing in different areas over hours.

PARENT EDUCATION

- Milia is a benign self-limiting rash that disappears within a few months without leaving any scars. No drug therapy is required and use of nonprescription rash medications is not recommended.
- Neonatal acne resolves on its own in weeks. Oils and lotions do not help and may actually aggravate the acne.
- Mongolian spots are likely to fade over time and may disappear by age 7 to 13 years.
- ETN will usually disappear within 2 weeks.

109 CHILDHOOD HEMANGIOMAS AND VASCULAR MALFORMATIONS

Richard P. Usatine, MD
Megha Madhukar, MD

PATIENT STORY

A baby girl is brought to the office because her mother is concerned over the growing strawberry hemangioma on her face. Her mother is reassured that most of these childhood hemangiomas regress over time and that there is no need for immediate treatment (**Figure 109-1**).

INTRODUCTION

Hemangiomas are the most common benign tumors of infancy. They can be problematic if they block vision or interfere with any vital function. Most hemangiomas are small and of cosmetic concern only.

SYNONYMS

Infantile hemangiomas, angiomas. Strawberry hemangiomas are also called superficial hemangiomas of infancy. Cavernous hemangiomas are also called deep hemangiomas of infancy.

EPIDEMIOLOGY

- Approximately 30% of hemangiomas are present at birth; the other 70% appear within the first few weeks of life.
- Hemangiomas occur more commonly in fair-skinned, premature, female infants. In one study, the mothers of children with hemangiomas are of higher maternal age, have a higher incidence of preeclampsia and placenta previa, and are more likely to have had multiple gestation pregnancies.¹
- There is an increased incidence of vascular anomalies in the families of children born with hemangiomas.¹
- The data are mixed as to whether chorionic villus sampling may play a role in the formation of hemangiomas.¹
- Females are affected more often than males (2.4:1).¹

ETIOLOGY AND PATHOPHYSIOLOGY

- Hemangiomas consist of an abnormally dense group of dilated blood vessels. Most childhood hemangiomas are thought to occur sporadically.
- Hemangiomas are characterized by an initial phase of rapid proliferation, followed by spontaneous and slow involution, often

FIGURE 109-1 Strawberry hemangioma on the face causing no functional problems. Treatment is reassurance and watchful waiting. (Courtesy of Richard P. Usatine, MD.)

leading to complete regression. Most childhood hemangiomas are small and innocuous, but some grow to threaten a particular function (**Figure 109-2**) or even life.

- Rapid growth during the first month of life is the historical hallmark of hemangiomas, when rapidly dividing endothelial cells are responsible for the enlargement of these lesions. The hemangiomas become elevated and may take on numerous morphologies (dome-shaped, lobulated, plaque-like, and/or tumoral). The proliferation phase occurs during the first year, with most growth taking place during the first 6 months of life. Proliferation then slows and the hemangioma begins to involute.
- The involutorial phase may be rapid or prolonged. No specific feature has been identified in explaining the rate or completeness of involution. However, in one type of hemangioma, the rapidly involuting congenital hemangioma, the proliferation phase occurs entirely in utero such that the lesion is fully developed at birth, followed by complete involution during the second year of life.¹
- A good rule of thumb is 50% of childhood hemangiomas will involute by age 5 years, 70% by age 7 years, and the remainder of childhood hemangiomas will take an additional 3 to 5 years to complete the process of involution.¹
- Of the lesions that have involuted by age 6 years, 38% will leave residual evidence of the hemangioma in the form of a scar, telangiectasia, or redundant, “bag-like” skin. The chance of a permanent scar increases the longer it takes to involute. For example, of the lesions that involute after age 6 years, 80% may exhibit a cosmetic deformity.¹

DIAGNOSIS

CLINICAL FEATURES

Early lesions may be subtle, resembling a scratch or bruise, or alternatively may look like a small patch of telangiectasias or an area of hypopigmentation. Hemangiomas can start off as a flat red mark, but as proliferation ensues, it grows to become a spongy mass protruding from the skin. The earliest sign of a hemangioma is blanching of the involved skin with a few fine telangiectasias followed by a red macule. Rarely, a shallow ulceration may be the first sign of an incipient hemangioma.¹ Hemangiomas are typically diagnosed based on appearance, rarely warranting further diagnostic tests.

Hemangiomas may be superficial, deep, or a combination of both. Superficial hemangiomas are well defined, bright red, and appear as nodules or plaques located above clinically normal skin (**Figures 109-1 to 109-3**). Deep hemangiomas are raised flesh-colored nodules, which often have a bluish hue and feel firm and rubbery (**Figure 109-4**).

Most are clinically insignificant unless they impinge on vital structures, ulcerate, bleed, incite a consumptive coagulopathy, or cause high output cardiac failure or structural abnormalities. Blocking vision is a common reason needed for treatment (**Figure 109-2**).

TYPICAL DISTRIBUTION

Anywhere on the body, most often on the face, scalp, back, or chest.

IMAGING

Most hemangiomas of infancy do not need imaging. If the hemangioma is very large, deep or undefined, MRI with and without IV

FIGURE 109-2 Large hemangioma on the face needing immediate treatment to prevent amblyopia in the left eye. Although this hemangioma follows the V1 dermatome, this is not a port-wine stain and the patient does not have Sturge-Weber syndrome. (Courtesy of Richard P. Usatine, MD.)

FIGURE 109-3 Strawberry hemangioma present since birth on the face of a 22-month-old girl. Although it is close to her eye, her vision has never been occluded. She has been followed by ophthalmology and no active treatment was recommended. The hemangioma grew larger during the first year of life and is now beginning to involute without treatment. (Courtesy of Richard P. Usatine, MD.)

gadolinium helps delineate the location and extent of the hemangioma while also differentiating them from high flow vascular lesions, like arteriovenous malformations.¹ Ultrasound is a useful tool to differentiate hemangiomas from other subcutaneous structures such as cysts and lymph nodes as well as from other soft-tissue masses.¹

Plain radiography may be useful for evaluating hemangiomas that impinge on an airway.¹

BIOPSY

Biopsies are rarely needed and can be risky because vascular lesions may bleed profusely. If a biopsy is being considered, it might be best to refer to a specialist.

DIFFERENTIAL DIAGNOSIS

- Superficial capillary malformations that are frequently seen in infants include those above the eyelids and nape of the neck. These are called *salmon patches* and are not dangerous. The “angel’s kisses” on the eyelids usually disappear by age 2 years. The “stork bites” may last into adulthood but are rarely an issue because they often get covered by hair (**Figures 109-5** and **109-6**). These capillary malformations are a variant of nevus flammeus or port-wine stain. They are macular, sharply circumscribed, pink to purple, and varied in size (see Chapter 202, Hereditary and Congenital Vascular Skin Lesions).
- Blue rubber bleb nevus syndrome—Bluish cutaneous vascular malformations that empty with pressure, texture resembles rubbery nodules, similar to deep hemangiomas.²
- Maffucci syndrome—Rare congenital nonhereditary mesodermal dysplasia characterized by multiple enchondromata, cutaneous hemangiomas, and more recently spindle cell hemangiomas.³ It is important to identify Maffucci syndrome early because it is associated with an increased risk of malignancy. May appear as multiple vascular malformations of the skin with a “grape-like” appearance (see Chapter 202, Hereditary and Congenital Vascular Skin Lesions).
- Angiosarcoma—Rare, malignant endothelial tumor characterized as ill-defined red patches, plaques, or nodules (see Chapter 201, Acquired Vascular Skin Lesions).⁴
- Arteriovenous malformation—Benign, single red papules on head or neck, may be cutaneous or mucosal.⁴
- Infantile fibrosarcoma—A rare and highly malignant tumor of childhood that may take on the form of a highly vascularized mass, resembling a hemangioma, especially after a hemangioma has ulcerated as a result of rapid proliferation.⁵

MANAGEMENT

- The majority of hemangiomas will eventually involute without complications and require no treatment, but approximately 20% cause complications like ulcerations, irreversible cutaneous expansion, or threaten vital structures such as the eyes, nose, or airways.⁶
- Any large segmental hemangioma on the face could be part of the PHACE (posterior fossa malformations, hemangiomas, arterial anomalies, coarctation of aorta, cardiac defects, eye abnormalities)

FIGURE 109-4 Deep (cavernous) hemangioma on the arm in a 9-month-old child. Treatment is watchful waiting. (Courtesy of Richard P. Usatine, MD.)

FIGURE 109-5 Salmon patch (a variant of nevus flammeus) on the upper eyelid called an “angel’s kiss.” These resolve by age 2 years. (Courtesy of Richard P. Usatine, MD.)

FIGURE 109-6 Salmon patch (a variant of nevus flammeus) on the neck of this young child called a “stork bite.” These vascular malformations persist into adulthood. (Courtesy of Richard P. Usatine, MD.)

syndrome and therefore will need evaluation of the eyes, central nervous system (CNS), and heart.

- **Posterior fossa**—Brain malformations present at birth.
- **Hemangioma**—Segmental hemangioma covers a large area on the head or neck (greater than 5 cm).
- **Arterial lesions**—Abnormalities of the blood vessels in the neck or head.
- **Cardiac abnormalities/aortic coarctation.**
- **Eye abnormalities.**
- Any lower face or beard hemangioma can be a marker for laryngeal hemangiomatosis. Snoring in such a child can be a bad sign. Refer to a head and neck surgeon.
- Hemangiomas in trauma-prone areas are most likely to ulcerate. These include the diaper area (**Figure 109-7**) and the back of the head. Small ulcerations can be treated with topical mupirocin in morning and metronidazole gel in the evening. **SOR C**
- Propranolol is now the first line of therapy for function-impairing and rapidly proliferating infantile hemangiomas.²⁻⁴ It has been successfully used to treat periorbital infantile hemangiomas and other problematic infantile hemangiomas (**Figure 109-8**).²⁻⁴ **SOR B**
- Propranolol (20 mg/5 mL) is given orally starting with 1 mg/kg per day divided into qid dosing. It is advisable to monitor for hypoglycemia and low blood pressure even though this treatment has been found to be safe in a number of studies.²⁻⁴ If the child is tolerating the treatment well, the dose may be increased to the recommended maintenance dose of 1.5 to 2 mg/kg per day in divided doses.^{2,4} Treatment should be maintained until the lesion is completely involuted or the child is 1 year of age.

FIGURE 109-7 Strawberry hemangioma in the perianal area of a 5-month-old girl. This is at high risk of ulceration. (Courtesy of Richard P. Usatine, MD.)

FIGURE 109-8 Large infantile hemangioma in which the child does not have the PHACE syndrome. However, urgent therapy was needed to shrink this hemangioma. **A.** Before propranolol therapy. **B.** After propranolol therapy. (Courtesy of John Browning, MD.)

- Prior to the discovery of the benefits and safety of propranolol as a first-line treatment, prednisone 3 to 5 mg/kg per day had been shown to provide an effective and rapid way of treating hemangiomas.⁷ **SOR B** In a study, 68% of patients receiving systemic corticosteroid treatment with oral prednisone experienced rapid and virtually complete involution of hemangiomas.⁷ Another 25% experienced significant regression, and treatment demonstrated no effect in 7% of patients. The authors recommended treating with oral prednisone for 6 to 8 weeks, and in more severe cases, for 12 weeks. Side effects include moon facies and irritability, which resolved once therapy was discontinued.⁷ Growth may be retarded temporarily.
- Ultrapotent topical corticosteroids have been found especially helpful in the treatment of small hemangiomas, especially periocular hemangiomas and those at sites prone to ulceration and disfigurement. Seventy-four percent of patients demonstrated good or at least partial response to treatment with the majority experiencing cessation of growth before what would have been expected for their age. Thinner, more superficial hemangiomas demonstrated better improvement than thicker, deeper lesions.⁸ **SOR B**
- Intralesional corticosteroid injections, composed of a mixture containing triamcinolone acetonide (20 mg average dose) and betamethasone acetate (3 mg average dose) with varying number of injections, have been found to successfully treat head and neck childhood hemangiomas in properly selected infants. In a research study, 13% of the hemangiomas treated with intralesional injections almost completely involuted, 32% showed greater than 50% reduction in volume, 32% showed definite but less than 50% reduction in volume, and 23% showed little to no decrease in size.⁹ **SOR B** Avoid intralesional steroids around eye.
- Treatment with flashlamp-pumped pulsed-dye laser has been found to be an effective treatment method for superficial cutaneous hemangiomas at sites of potential functional impairment and on the face. In a study, 76% of patients were found to have excellent or good results with the flashlamp-pumped pulsed-dye laser. Hemangiomas with a deep component do not seem to benefit from flashlamp-pumped pulsed-dye laser therapy to the same degree as a truly superficial hemangioma, as the laser is limited by its depth of vascular injury.¹² **SOR B**
- Facial hemangiomas causing severe functional disturbance and serious psychological distress are strong reasons to consider surgical excision before the child reaches the expected age of spontaneous regression. **SOR C**
- Large periocular hemangiomas demand prompt treatment to prevent debilitating consequences such as amblyopia (**Figure 109-2**). Early treatment is also recommended for proliferative labial tumors because not only do they have a tendency to bleed, but they also make eating difficult. Additionally, early treatment with a consideration for surgery is advised for hemangiomas located on the nasal tip as they regress slowly and may ultimately result in distortion of the nasal framework.¹³
- Laser surgery may be considered for selective ablation of vascular tissue, like ulcerated hemangiomas and thin superficial hemangiomas, especially when their locations may result in psychosocial distress for the patient, that is, facial hemangiomas. The pulsed-dye laser seems especially promising with its ability to selectively

damage blood vessels with minimal damage to surrounding tissues.¹⁴ This procedure is also associated with decreased pain and increased healing.¹⁴ **SOR B**

- Surgical excision of involuted hemangiomas is not uncommon to remove the residual tissue that may be causing cosmetic or functional impairment. Excision is performed in late involution to reduce the risk of hemorrhage.
- Depending on the location and how complex the hemangioma is, consultations with pediatric dermatologists, ophthalmologists, otolaryngologists, plastic surgeons, and pediatric neurosurgeons may be necessary to ensure proper care.

NEW TOPICAL THERAPY

- Topical timolol ophthalmic gel or solution has been shown in a number of studies to effectively treat infantile hemangiomas.^{15,16,17} **SOR B** One of the studies noted that predictors of better response were superficial type of hemangioma ($p = 0.01$), 0.5% timolol concentration ($p = 0.01$), and duration of use longer than 3 months ($p = 0.04$).¹⁶ **SOR B** Another study using 0.5% ophthalmic solution 3-4 times daily in patients with small superficial hemangiomas found that treatment was most effective in the early proliferative stage.¹⁵ **SOR B**

FOLLOW-UP

Watchful waiting and serial observations during well-child examinations are recommended for uncomplicated hemangiomas of infancy. Hemangiomas with complicating factors need close follow-up on an individual basis.

PATIENT EDUCATION

Hemangiomas are benign and not cancer. They are common and up to 1 in 10 white babies will have one. Most hemangiomas will go away spontaneously and not need treatment. For those needing treatments, there are new treatments that are safe and effective (oral propranolol and topical timolol).

110 PUSTULAR DISEASES OF CHILDHOOD

Andrew Shedd, MD
Richard P. Usatine, MD
Heidi Chumley, MD

PATIENT STORY

A 1-year-old boy is brought for a second opinion about the recurrent pruritic vesicles and pustules on his hands and feet. This is the third episode, and in both previous episodes, the physicians thought the child had scabies. The child was treated with permethrin both times and within 2 to 3 weeks the skin cleared. No other family members have had lesions or symptoms. **Figures 110-1 to 110-3** demonstrate a typical case of infantile acropustulosis that is often misdiagnosed as scabies. Although the condition can be recurrent, it is ultimately self-limited and will resolve.

INTRODUCTION

Acropustulosis and transient neonatal pustular melanosis (TNPM) are pustular diseases that typically present in infancy. Acropustulosis is a pruritic vesiculopustular disease presenting between 2 and 10 months of age and remitting spontaneously by 36 months of age. TNPM is present at birth and characterized by 2- to 3-mm hyperpigmented macules and pustules. Acropustulosis may require symptomatic treatment of pruritus, but otherwise both illnesses are self-limiting.

EPIDEMIOLOGY

Acropustulosis:

- Rare, intensely pruritic, vesiculopustular disease of young children.¹
- Typically begins in the second or third months¹ of life and as late as 10 months of age.²
- Occur slightly more often in darker-skinned patients and males.¹
- Typically spontaneously remits by 6 to 36 months of life.²

Transient neonatal pustular melanosis:

- A disease of newborns.³
- Equal male-to-female ratio.³
- Seen in 4.4% of black infants and 0.6% of white infants.⁴
- Early, spontaneous remission.³

ETIOLOGY AND PATHOPHYSIOLOGY

Acropustulosis:

- The exact cause and mechanism have yet to be determined.⁵
- Some physicians speculate that it is a persistent reaction to scabies (“postscabies syndrome”). Suggestive of this infectious etiology,

FIGURE 110-1 Infantile acropustulosis (acropustulosis of infancy) on the foot of a 1-year-old boy. (Courtesy of Richard P. Usatine, MD.)

FIGURE 110-2 Acropustulosis with vesiculopustular eruption on the toes of the boy shown in Figure 110-1. (Courtesy of Richard P. Usatine, MD.)

infantile acropustulosis will occasionally be concurrently present amongst siblings. Also, patients diagnosed with this disorder frequently have received prior treatment for scabies, which may either provide evidence of an infectious etiology or demonstrate the frequent misdiagnosis, as in the patient above. Odom et al. concludes that in some cases, this disease may represent a hypersensitivity reaction to *Sarcoptes scabiei*.⁴

Transient neonatal pustular melanosis:

- The etiology is uncertain⁶; however, it may result from an obstruction of the pilosebaceous orifice.³

DIAGNOSIS

- Acropustulosis—A workup to rule out potentially serious infectious causes should be considered whenever confronted with a new pustular dermatosis early in a child's life. A workup might include a scraping for scabies, and KOH preparation as rapid diagnostic tests. If these studies are negative, the diagnosis may be made clinically as described below.
- TNPM—This diagnosis can often be made clinically. However, if performed, a Wright stain of the exudate will reveal a predominance of neutrophils with an occasional eosinophil, and the Gram stain will be negative.³

CLINICAL FEATURES

Acropustulosis:

- These vesiculopustular lesions begin around the second or third months of life and are typically concentrated on the hands and feet (Figures 110-1 to 110-3).¹
- They begin acutely as small pink papules and progress within 24 hours to pustules¹ of less than 5 mm in diameter.²
- Recurrent episodes of these intensely pruritic lesions typically last 10 days and may recur every 2 to 5 weeks,^{1,2} decreasing in frequency and severity² until spontaneous remission around 3 years of age.¹
- There may be a residual scale and postinflammatory hyperpigmentation.²

Transient neonatal pustular melanosis:

- This condition is characterized by the presence at birth of 2- to 3-mm macules and pustules⁴ on a nonerythematous base (Figures 110-4 and 110-5).⁷
- The lesions probably evolve prenatally⁷ and subsequently rupture postnatally in 1 to 2 days.
- They heal with hyperpigmented macules that fade by 3 months of age,³ with lighter-skinned patients experiencing less hyperpigmentation.⁷
- Sometimes, the only evidence of the disease is the presence of small, brown macules with a rim of scale at birth.⁷

TYPICAL DISTRIBUTION

- Acropustulosis—Although most commonly found on the palms and soles, the pustules may also be found on the dorsal surfaces of the hands and feet and occasionally the face, scalp, and trunk.⁵

FIGURE 110-3 Acropustulosis with pruritic eruption on the hand and wrist of the boy shown in Figures 110-1 and 110-2. (Courtesy of Richard P. Usatine, MD.)

FIGURE 110-4 Neonatal pustular melanosis on the hand of a newborn. (Courtesy of Dan Stulberg, MD.)

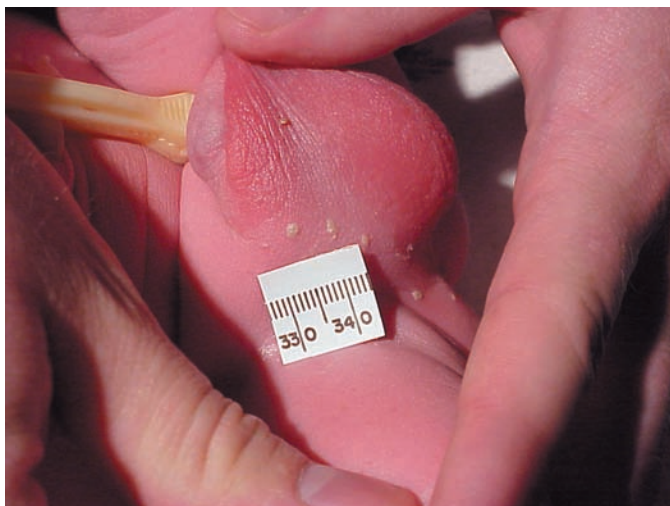

FIGURE 110-5 Neonatal pustular melanosis on scrotum of the same newborn. (Courtesy of Dan Stulberg, MD.)

- TNPM—They are most common on the face and chin; however, they may also be present on the neck, chest, sacrum, abdomen, and thighs.⁷

LABORATORY TESTING

- Acropustulosis—A blood count is not needed but might reveal a slight leukocytosis and frequently an eosinophilia. Stained smears of the lesions are also not needed but will demonstrate many neutrophils,¹ with some eosinophils possible early in the course.²
- TNPM—A Wright stain will reveal numerous neutrophils and some eosinophils, with a negative Gram stain.³ Blood counts should be normal and no laboratory workup is generally indicated.

DIFFERENTIAL DIAGNOSIS

- Scabies infestation—Characterized by pruritic, intraepidermal burrows and vesicles with scale and crust, most commonly found in the web spaces of the digits, wrists, elbow, genitals, and lower extremities. May be present in other family members, and is not present at birth. Microscopic examination of the scrapings of the burrows may reveal mites, feces, eggs, or all of the above.³ Acropustulosis will be refractory to all scabies therapies but scabies therapy may appear to work because each episode of acropustulosis is self-limited (see Chapter 143, Scabies).
- Erythema toxicum neonatorum—Appearing on the neonate 1 to 2 days after birth, this disease of unknown etiology causes 2- to 3-cm diffuse blotchy macules with 1- to 4-mm central vesicles. The lesions, which spare the palms and soles, contain a predominance of eosinophils and resolve spontaneously by 2 weeks of age (see Chapter 108, Normal Skin Changes).³
- Impetigo—A superficial infection of the skin with vesicles, bullae, and honey-colored crusts, caused by group A *Streptococcus*, or *Staphylococcus aureus*. Gram stain and culture should be positive (see Chapter 116, Impetigo).³
- Cutaneous candidiasis—Slightly pruritic areas of intensely erythematous papules, pustules, and plaques, possibly with white exudate, found around the genitals and folds of skin. *Candida* yeast forms present on KOH preparation or culture (see Chapter 136, Candidiasis).³
- Varicella—Characteristic “dewdrops on a rose petal” that develop in childhood. Uniformly distributed, pruritic, with known contacts likely. Now less common because of immunization (see Chapter 123, Chickenpox).
- Herpes—Grouped, painful vesicles on an erythematous base. May occur as gingivostomatitis in young children but rarely seen in the distribution of the pustular diseases of childhood. More likely to be vesicular rather than pustular (see Chapter 129, Herpes Simplex).
- Hand, foot, and mouth disease—This illness is caused by the coxsackievirus and produces papules and macules of the hands and feet that progress to flat vesicles before ulceration and eventual resolution. They typically affect the dorsum of the hands and feet and are also accompanied by painful oral lesions (see Chapter 128, Hand, Foot, and Mouth Disease).³
- Psoriasis, pustular—This severe form of psoriasis is rare in children and is characterized by the acute appearance of diffuse, painful,

pinpoint pustules with high fever, fatigue, and anorexia (see Chapter 152, Psoriasis).¹

MANAGEMENT

Acropustulosis:

- Corticosteroids (topical and oral) generally are not effective,¹ and not necessary in management.⁵ SOR C
- Oral antihistamines may be helpful in controlling pruritus.¹ SOR C
- Pramoxine, lotion or cream, may be used topically for control of itching as it works by a different mechanism than antihistamines.⁵ SOR C
- Dapsone (1 to 2 mg/kg per day, maximum dose of 100 mg/day)⁵ has been used with good results. However, the risks of complications are generally considered to outweigh the benefits, unless the pruritus is debilitating.¹ SOR C

Transient neonatal pustular melanosis:

- No treatment is necessary. The parents should be reassured that the condition is benign and will resolve spontaneously with eventual normalization of any hyperpigmented macules.⁶ SOR B

PROGNOSIS

- Acropustulosis resolves spontaneously by 6 to 36 months of age.
- TNPM resolves spontaneously by 3 months of age.

FOLLOW-UP

Acropustulosis may require initial follow-up for control of symptoms and assurance of a stable disease course. With symptoms controlled, follow-up may be unnecessary as the child ages and the disease decreases in severity and frequency. If dapsone is prescribed, proper monitoring is indicated.

TNPM needs no specific follow-up other than normal well-child care.

PATIENT EDUCATION

Once other conditions have been ruled out, reassurance that these diseases are self-limited is the most important piece of information to communicate to the family.

111 DIAPER RASH AND PERIANAL DERMATITIS

Bridget Malit, MD
Julie Scott Taylor, MD, MSc

PATIENT STORY

A 2-month-old baby girl was brought to the office with a severe diaper rash that was not getting better with Desitin. Upon examination, the physician noted a white coating on the tongue and buccal mucosa. The diaper area was red with skin erosions and satellite lesions (**Figure 111-1**). The whole picture is consistent with candidiasis of the mouth (thrush) and the diaper region. The child was treated with oral nystatin suspension and topical clotrimazole cream in the diaper area with good results.

INTRODUCTION

Diaper rash is a general term used to describe any type of red or inflammatory skin rash that is located in the diaper area.

SYNONYMS

Diaper dermatitis, napkin dermatitis.

EPIDEMIOLOGY

- Diaper dermatitis is the most common dermatitis of infancy.
- Variability in prevalence of 4% to 35% among children in their first 2 years of life in different studies.¹
- Diaper rash is thought to be present in 25% of children presenting for outpatient visits.²
- No differences in prevalence between genders or among ethnic groups.
- One study showed an incidence of 19.4% in children ages 3 to 6 months.¹
- Higher incidence among formula-fed compared with breastfed infants.¹
- Condition typically begins around age 3 weeks, peaks at age 9 to 12 months, and then decreases with age until it resolves completely with toilet training.
- Individual episodes last from 1 day to 2 weeks.
- Aggravating factors include poor skin care, diarrhea, recent antibiotic use, and urinary tract abnormalities.
- Perianal streptococcal dermatitis occurs in children between 6 months and 10 years of age (**Figures 111-2 and 111-3**).

FIGURE 111-1 *Candida* diaper dermatitis in an infant who has oral thrush. (Courtesy of Richard P. Usatine, MD.)

ETIOLOGY AND PATHOPHYSIOLOGY

- Primary diaper dermatitis—An acute skin inflammation in the diaper area with a multifactorial etiology.³ The main cause is irritation of thin skin as a result of prolonged contact with moisture including feces and urine. The multiple factors involved are:
 1. Occlusion/lack of exposure to air.
 2. Friction and mechanical trauma.
 3. Local irritants—Fecal proteases and lipases.
 4. Increased pH.
 5. Maceration of the stratum corneum with loss of the protective barrier function of skin.
- Irritant diaper dermatitis (IDD) is a combination of intertrigo (wet skin damaged from chafing) and miliaria (heat rash) when eccrine glands become obstructed from excessive hydration. It is a noninfectious, nonallergic, often asymptomatic contact dermatitis that typically lasts for less than 3 days after a change in diaper practices.
- Candidal diaper dermatitis—Within 3 days, 45% to 75% of diaper rashes are colonized with *Candida albicans* of fecal origin.
- Bacterial diaper dermatitis may be a secondary infection caused by *Staphylococcus aureus* or *Streptococcus pyogenes*. Other common bacterial isolates include *Escherichia coli*, *Peptostreptococcus*, and *Bacteroides*. Usually occurs during the warm summer months.
- Perianal streptococcal dermatitis is caused by group A β -hemolytic streptococci (Figures 111-2 and 111-3).

RISK FACTORS

- Diarrhea.
- Formula-fed infants.
- Recent antibiotic use.
- Urinary tract abnormalities.
- Poor skin care.

DIAGNOSIS

CLINICAL FEATURES

- IDD begins with shiny erythema with or without scale and poorly demarcated margins on the convex skin surfaces in areas covered by diapers. Moderate cases can have papules, plaques, vesicles, and small superficial erosions that can progress to well-demarcated ulcerated nodules typically with sparing of skin folds (Figure 111-4).
- Pustules or papules beyond the rash border (called “satellite lesions”), involvement of the skin folds, and white scaling all indicate a fungal infection with *Candida* (Figure 111-5).
- Secondary bacterial infections can have redness, honey-colored crusting, swelling, red streaking, and/or purulent discharge. With impetigo in the diaper area, bullae are not usually intact but instead present as superficial erosions.
- Perianal streptococcal dermatitis is a bright red, sharply demarcated rash sometimes associated with blood-streaked stools (Figure 111-2).

FIGURE 111-2 Perianal dermatitis caused by group A β -hemolytic streptococci. (From Sheth S, Schechtman AD. *Itchy perianal erythema*. *J Fam Pract*. 2007;56(12):1025-1027. Reproduced with permission from Frontline Medical Communications.)

FIGURE 111-3 A positive rapid strep test taken from a swab of the perianal area of the infant in the previous photo. (From Sheth S, Schechtman AD. *Itchy perianal erythema*. *J Fam Pract*. 2007;56(12):1025-1027. Reproduced with permission from Frontline Medical Communications.)

FIGURE 111-4 Irritant diaper dermatitis precipitated by diarrhea secondary to amoxicillin-clavulanate prescribed to treat otitis media. Note the absence of satellite lesions. (Courtesy of Richard P. Usatine, MD.)

TYPICAL DISTRIBUTION

Diaper dermatitis is primarily found on the buttocks, the genitalia, the mons pubis and lower abdomen, and the medial thighs. Be sure to evaluate for rashes outside of the diaper area as well. If *Candida* is suspected, the oropharynx should be inspected for signs of thrush, such as adherent white plaques on the mucosa.

LABORATORY STUDIES

Clinical diagnosis is based primarily on the physical examination. Rarely indicated tests that are occasionally used in more complicated cases include potassium hydroxide preparation for fungal elements, mineral oil preparation for scabies, complete blood count with differential, zinc level, or skin biopsy (**Figure 111-6**). A rapid strep test can be used to diagnose perianal streptococcal dermatitis (**Figures 111-2 and 111-3**).

DIFFERENTIAL DIAGNOSIS

There are two distinctive severe variants of IDD. Jacquet's diaper dermatitis (dermatitis syphiloides posterosiva or erosive variant) is a term used to describe severe, slow-healing, noduloerosive lesions with heaped-up borders seen in children with persistent diarrhea.⁴ Granuloma gluteale infantum is a rare and poorly understood primary diaper dermatitis that presents with granulomatous nodules that can have large, raised, purple erosions with rolled margins. It resolves spontaneously over the course of a few months once the causative agent is discovered and removed, often with residual scarring and hyperpigmentation.⁵

Perianal pseudoverrucous papules are shiny, smooth, red, moist, flat-topped lesions that are commonly confused with the genital warts that occur in the context of Hirschsprung disease.

Secondary diaper dermatitis is an eruption in the diaper area with a defined etiology. Atopic dermatitis, seborrheic dermatitis, and psoriasis are examples of rashes that can appear anywhere on the body and can be exaggerated in the groin as a result of wearing diapers. Family history of atopy or psoriasis and rash in other locations besides the groin can be helpful.

Congenital syphilis, scabies, HIV, Langerhans cell histiocytosis, and acrodermatitis enteropathica are examples of rashes in the diaper area unrelated to the diaper. Allergic contact dermatitis as a result of an allergen in the diaper itself is possible but rare.

Suspect acrodermatitis enteropathica caused by zinc deficiency when the diaper dermatitis is severe and accompanied by perioral dermatitis (**Figure 111-6**). The serum zinc level will be low and zinc supplementation will be needed.

MANAGEMENT

TREATMENT

- Parental behavior change to keep the skin as exposed and dry as possible. **SOR B** Frequent diaper changes (as soon as they are wet or soiled and at least every 3 to 4 hours); use disposable diapers. **SOR B** Frequent gentle cleaning of the affected area with lukewarm tap water instead of commercial wipes containing alcohol

FIGURE 111-5 Close-up of a *Candida* diaper dermatitis in a 5-month-old infant. Note the superficial scaling around the satellite lesions. (Courtesy of Richard P. Usatine, MD.)

FIGURE 111-6 Acrodermatitis enteropathica caused by zinc deficiency. The child also had perioral dermatitis that appeared similar to the diaper dermatitis. (Courtesy of Richard P. Usatine, MD.)

and pat dry. A squeeze bottle with lukewarm water can be used to avoid rubbing the delicate skin.

- Superabsorbent diapers that pull moisture away from the skin are helpful.¹ **SOR B**
- Apply barrier preparations, including zinc oxide paste, petroleum jelly, Vitamin A & D ointment, or Burow solution, to affected area after each diaper change.¹ **SOR B** Pastes are better than ointments, which, in turn, are better than creams or lotions. Avoid products with fragrances or preservatives to minimize allergic potential. Apply thickly like “icing on a cake.” These barrier preparations should be used *on top* of other indicated therapies.
- For moderate to severe inflammation, consider a nonfluorinated, low-potency topical steroid such as 1% hydrocortisone ointment (up to 3 times daily) to the affected area until the dermatitis is gone. To avoid skin erosions, atrophy, and striae, it is best to not go beyond 2 weeks of therapy with any topical steroid on a baby’s bottom.
- For *Candida*, use topical nonprescription antifungal creams such as clotrimazole, miconazole after every diaper change until the rash resolves. **SOR B** For concomitant oral thrush, treat with oral nystatin swish and swallow 4 times daily.
- Avoid combination antifungal–steroid agents that contain steroids stronger than hydrocortisone (e.g., Lotrisone). Potent topical steroids can cause striae and skin erosions, hypothalamus–pituitary–adrenal axis suppression, and Cushing syndrome.¹
- For mild bacterial infections, use topical antibiotic ointments such as bacitracin or mupirocin after every diaper change until the rash resolves. **SOR B**
- For more severe bacterial infections, consider a broad-spectrum oral antibiotic such as amoxicillin-clavulanate. Perianal bacterial dermatitis has been reported to be predominantly caused by *S. aureus*.⁶ Oral cephalexin is a good choice because it covers *S. aureus* and group A β -hemolytic streptococcus. If methicillin-resistant *S. aureus* (MRSA) is suspected, consider trimethoprim-sulfamethoxazole. **SOR B**
- Ciclopirox 0.77% topical suspension (Loprox), a broad-spectrum agent with antifungal, antibacterial, and antiinflammatory properties, was used safely and effectively in 1 trial of 44 children to treat diaper dermatitis caused by *Candida*.¹ **SOR B**
- Recommend dye-free diapers for allergic contact dermatitis. **SOR B**

PREVENTION AND ROUTINE SKIN CARE

- Keep the diaper region as dry and clean as possible.
- Promote the use of barrier preparations daily to maintain skin integrity.
- There is no evidence to suggest that topical vitamin A prevents diaper dermatitis.⁷ **SOR B**
- Disposable diapers—Although many individual trials show benefits, a 2006 Cochrane Review found that there is not enough evidence from good quality, randomized, controlled trials to support or refute the use and type of disposable diapers for the prevention of diaper dermatitis in infants.⁸ **SOR B**

PROGNOSIS

Diaper dermatitis has an excellent prognosis when treated as above.

FOLLOW-UP

No follow-up needed unless the rash worsens or persists. The exception is severe bacterial infection where follow-up is recommended because recurrences are common.

PATIENT (PARENT) EDUCATION

Prevention and early treatment are the best strategies. Keep the child's diaper area as clean, cool, and dry as possible with frequent diaper changes. Do *not* use creams that contain boric acid, camphor, phenol, methyl salicylate, compound of benzoin, or talcum powder or cornstarch. Reassure parents that, although this common condition is sometimes distressing for parents and uncomfortable for children, it is rarely dangerous.

SECTION 2 ACNEIFORM DISORDERS

112 ACNE VULGARIS

Richard P. Usatine, MD

PATIENT STORY

A 16-year-old boy (**Figure 112-1**) with severe nodulocystic acne and scarring presents for treatment. After trying oral antibiotics, topical retinoids, and topical benzyl peroxide with no significant benefit, the patient and his mother request isotretinoin (Accutane). After 4 months of isotretinoin, the nodules and cysts cleared and there remained only a few papules (**Figure 112-2**). He is much happier and more confident about his appearance. The skin cleared fully after the last month of isotretinoin.

INTRODUCTION

Acne is an obstructive and inflammatory disease of the pilosebaceous unit predominantly found on the face of adolescents. However, it can occur at any age and often involves the trunk in addition to the face.

EPIDEMIOLOGY

Acne vulgaris affects more than 80% of teenagers, and persists beyond the age of 25 years in 3% of men and 12% of women.¹

ETIOLOGY AND PATHOPHYSIOLOGY

The four most important steps in acne pathogenesis:

1. Sebum overproduction related to androgenic hormones and genetics.
2. Abnormal desquamation of the follicular epithelium (keratin plugging).
3. *Propionibacterium acnes* proliferation.
4. Follicular obstruction, which can lead to inflammation and follicular disruption.

Neonatal acne is thought to be related to maternal hormones and is temporary (**Figure 112-3**).

Acne can be precipitated by mechanical pressure as with a helmet strap (**Figure 112-4**) and medications such as phenytoin and lithium (**Figure 112-5**).

There are some studies that suggest that consumption of large quantities of milk (especially skim milk) increase the risk for acne in teenagers.²

FIGURE 112-1 Severe nodulocystic acne with scarring in a 16-year-old boy. (Courtesy of Richard P. Usatine, MD.)

FIGURE 112-2 A happier boy now that his nodules and cysts have cleared at the start of the fifth month of isotretinoin treatment. (Courtesy of Richard P. Usatine, MD.)

DIAGNOSIS

CLINICAL FEATURES

Morphology of acne includes comedones, papules, pustules, nodules, and cysts.

- Obstructive acne = comedonal acne = noninflammatory acne and consists of only comedones (**Figure 112-6**).
- Open comedones are blackheads and closed comedones are called whiteheads and look like small papules.
- Inflammatory acne has papules, pustules, nodules, and cysts in addition to comedones (**Figure 112-5**).

TYPICAL DISTRIBUTION

Face, back, chest, and neck.

LABORATORY STUDIES

None unless you suspect androgen excess and/or polycystic ovarian syndrome (PCOS).³ **SOR A** Obtain testosterone and DHEA-S levels if you suspect androgen excess and/or PCOS.

Consider follicle-stimulating hormone (FSH) and luteinizing hormone (LH) levels if you suspect PCOS.

DIFFERENTIAL DIAGNOSIS

- Acne conglobata is an uncommon and unusually severe form of acne characterized by multiple comedones, cysts, sinus tracks, and abscesses. The inflammatory lesions and scars can lead to significant disfigurement.⁴ Sinus tracks can form with multiple openings that drain foul-smelling purulent material (**Figures 112-7, 112-8 and 112-9**). The comedones and nodules are usually found on the chest, the shoulders, the back, the buttocks, and the face. In some cases acne conglobata is part of a follicular occlusion triad including hidradenitis and dissecting cellulitis of the scalp (**Figure 112-9**).
- Acne fulminans is characterized by sudden onset ulcerative crusting cystic acne, mostly on the chest and back (**Figures 112-10 and 112-11**).⁵ Fever, malaise, nausea, arthralgia, myalgia, and weight loss are common. Leukocytosis and elevated erythrocyte sedimentation rate are usually found. There may also be focal osteolytic lesions. The term *acne fulminans* may also be used in cases of severe aggravation of acne without systemic features.⁵
- Rosacea can resemble acne by having papules and pustules on the face. It is usually seen in older adults with prominent erythema and telangiectasias. Rosacea does not include comedones and may have ocular or nasal manifestations (Chapter 113, Rosacea). Rosacea fulminans or pyoderma faciale has features of severe acne and rosacea (**Figure 112-12**).
- Folliculitis on the back may be confused with acne. Look for hairs centrally located in the inflammatory papules of folliculitis to help distinguish it from acne. Acne on the back usually accompanies acne on the face as well (Chapter 117, Folliculitis).
- Acne keloidalis nuchae consists of papules, pustules, nodules, and keloidal tissue found at the posterior hairline. It is most often seen in men of color after shaving the hair at the nape of the neck (Chapter 114, Pseudofolliculitis and Acne Keloidalis Nuchae).

FIGURE 112-3 Neonatal acne in a healthy 2-week-old infant that resolved without treatment. (Courtesy of Richard P. Usatine, MD.)

FIGURE 112-4 Inflammatory acne showing pustules and nodules in a 17-year-old boy who uses a helmet while playing football in high school. (Courtesy of Richard P. Usatine, MD.)

A

B

FIGURE 112-7 A. Acne conglobata in a 16-year-old boy. He has severe cysts on his face with sinus tracks between them. He required many weeks of oral prednisone before isotretinoin was started. His acne cleared completely with his treatment. B. Acne conglobata cleared with minimal scarring after oral prednisone and 5 months of isotretinoin therapy. (Courtesy of Richard P. Usatine, MD.)

FIGURE 112-5 Severe inflammatory acne in a young adult. His acne worsened when he was started on phenytoin for his seizure disorder. (Courtesy of Richard P. Usatine, MD.)

FIGURE 112-6 Comedonal acne in a 15-year-old girl. Open comedones (blackheads) and closed comedones (whiteheads) are visible on her forehead. (Courtesy of Richard P. Usatine, MD.)

FIGURE 112-8 Acne conglobata in a 42-year-old woman showing communicating sinus tracks between cysts. There is pus draining from one of the sinus tracts on the right side of the neck. (Courtesy of Richard P. Usatine, MD.)

- Actinic comedones (blackheads) are related to sun exposure and are seen later in life (**Figure 112-13**).

MANAGEMENT

Treatment is based on type of acne and severity. Categories to choose from are topical retinoids, topical antimicrobials, systemic antimicrobials, hormonal therapy, oral isotretinoin, and injection therapy.

MEDICATIONS FOR ACNE THERAPY

In a review of 250 comparisons, the Agency for Healthcare Research and Quality found 14 had evidence of level A.⁶ These comparisons demonstrated the efficacy over vehicle or placebo control of topical clindamycin, topical erythromycin, benzoyl peroxide, topical tretinoin, oral tetracycline, and norgestimate/ethinyl estradiol.⁴ Level A conclusions demonstrating equivalence include: Benzoyl peroxide at various strengths was equally efficacious in mild/moderate acne; adapalene and tretinoin were equally efficacious.⁶ **SOR A**

Topical

- Benzoyl peroxide—Antimicrobial effect (gel, cream, lotion) (2.5%, 5%, 10%) 10% causes more irritation and is not more effective.¹ **SOR A**
- Topical antibiotics—Clindamycin and erythromycin are the mainstays of treatment.
- Erythromycin—Solution, gel.³ **SOR A**
- Clindamycin—Solution, gel, lotion.³ **SOR A**
- Benzamycin gel—Erythromycin 3%, benzoyl peroxide 5%.³ **SOR A**
- BenzaClin gel—Clindamycin 1%, benzoyl peroxide 5%.³ **SOR A**
- Dapsone 5% gel.⁷ **SOR B**

Retinoids:

- Tretinoin (Retin-A) gel, cream, liquid, micronized.¹ **SOR A**
- Adapalene gel—Less irritating than tretinoin.¹ **SOR A**
- Tazarotene—Strongest topical retinoid with greatest risk of irritation.⁸ **SOR A**

Topical retinoids will often result in skin irritation during the first 2 to 3 months of treatment, but new systematic reviews do not demonstrate that they worsen acne lesion counts during the initial period of use.²

- Azelaic acid—Useful to treat spotty hyperpigmentation and acne (**Figure 112-14**).³ **SOR B**

Systemic

- Oral antibiotics.
 - Tetracycline 500 mg qd-bid—Inexpensive, absorbed best on an empty stomach.³ **SOR A**
 - Doxycycline 40 to 100 mg qd bid—Inexpensive, well tolerated, can take with food and increases sun sensitivity.³ **SOR A**
 - Minocycline 50 to 100 mg qd bid—Expensive, not proven to be better than other systemic antibiotics including tetracycline.^{3,9} **SOR A**
 - Erythromycin 250 to 500 mg bid—Inexpensive, frequent gastrointestinal (GI) disturbance but can be used in pregnancy.³ **SOR A**

FIGURE 112-9 Acne conglobata in a 53-year-old man covered with open comedones and cysts on his back. He has the follicular occlusion triad including hidradenitis, dissecting cellulitis of the scalp and acne conglobata. (From Grunwald MH, Amichai B. Nodulo-cystic eruption with musculoskeletal pain. *J Fam Pract.* 2007;56(3):205-206. Reproduced with permission from Frontline Medical Communications.)

FIGURE 112-10 Acne fulminans in a 17-year-old boy. He was on isotretinoin when he developed worsening of his acne with polymyalgia and arthralgia. He presented with numerous nodules and cysts covered by hemorrhagic crusts on his chest and back. (From Grunwald MH, Amichai B. Nodulo-cystic eruption with musculoskeletal pain. *J Fam Pract.* 2007;56:205-206. Reproduced with permission from Frontline Medical Communications.)

FIGURE 112-11 Acne fulminans with severe rapidly worsening truncal acne in a 15-year-old boy. He did not have fever or bone pain but had a white blood cell count of 17,000. He responded rapidly to prednisone and was started on isotretinoin. The ulcers and granulation tissue worsened initially on isotretinoin but prednisone helped to get this under control. (Courtesy of Richard P. Usatine, MD.)

- Trimethoprim/sulfamethoxazole DS bid—Effective but risk of Stevens-Johnson syndrome is real. Reserve for short courses in particularly severe and resistant cases.³ **SOR A**

Oral azithromycin has been prescribed in pulse dosing for acne in a number of small poorly done studies and has not been found to be better than oral doxycycline.¹⁰

- Isotretinoin (Accutane) is the most powerful treatment for acne. It is especially useful for cystic and scarring acne that has not responded to other therapies.³ **SOR A** Dosed at approximately 1 mg/kg per day for 5 months. Women of childbearing age must use two forms of contraception. Monitor for depression.
- The U.S. Food and Drug Administration requires that prescribers of isotretinoin, patients who take isotretinoin, and pharmacists who dispense isotretinoin all must register with the iPLEDGE system (www.ipledgeprogram.com).
- Hormonal treatments:
 - Oral contraceptives only for females—Choose ones with low androgenic effect.³ **SOR A** FDA-approved oral contraceptives are Ortho Tri-Cyclen, Yaz, and Estrostep. Other oral contraceptives with similar formulations also help acne in women even though these have not received FDA approval for this indication. Note Yaz and Yasmin have progestin drospirenone, which is derived from 17 α -spiro lactone. It shares an antiandrogenic effect with spironolactone.
 - Spironolactone may be used for adult women when other therapies fail.^{3,11,12} This may be especially useful if the patient has hirsutism. Standard dosing is 50 to 200 mg/day. May start with 25 mg bid and monitor for hyperkalemia. The risk of hyperkalemia increases with a higher dose. Titrate up as needed and tolerated.³ **SOR B** A recent systematic review failed to show a benefit for spironolactone in acne even though it was found to decrease hirsutism.¹³
 - One small prospective study of 27 women with severe papular and nodulocystic acne used a combination of EE/DRSP (Yasmin) and spironolactone 100 mg daily. Eighty-five percent of subjects were entirely clear of acne lesions or had excellent improvement and there was no significant elevation of serum potassium.¹⁴

COMPLEMENTARY AND ALTERNATIVE THERAPY

Tea tree oil 5% gel.¹⁵ **SOR B**

Steroid injection therapy

For painful nodules and cysts. **SOR C** Be careful to avoid producing skin atrophy.

- Dilute 0.1 cc of 10 mg/cc triamcinolone acetonide (Kenalog) with 0.4 cc of sterile saline for a 2 mg/cc suspension.
- Inject 0.1 cc with a 1-cc tuberculin syringe into each nodule using a 30-gauge needle (**Figure 112-15**).

ACNE THERAPY BY SEVERITY

Comedonal acne (Figure 112-6).

- Topical retinoid or azelaic acid.
- No need for antibiotics or antimicrobials—Do not need to kill *P. acnes*.

FIGURE 112-12 Pyoderma faciale is almost exclusively seen in adult women. It can present with severe cystic facial acne often in a malar distribution. It also is called rosacea fulminans. It started abruptly 6 months before and her antinuclear antibody was normal. (Courtesy of Richard P. Usatine, MD.)

FIGURE 112-13 Actinic comedones related to sun exposure in an older man. These are typically seen on the side of the face clustering around the eyes. (Courtesy of Richard P. Usatine, MD.)

Mild papulopustular

- Topical antibiotics and benzoyl peroxide.
- Topical retinoid or azelaic acid.
- May add oral antibiotics if topical agents are not working.

Papulopustular or nodulocystic acne—moderate to severe—inflammatory

- Topical antibiotic, benzoyl peroxide, and oral antibiotic.
- Oral antibiotics are often essential at this stage.
- Topical retinoid or azelaic acid.
- Steroid injection therapy—For painful nodules and cysts.

Severe cystic or scarring acne

- Isotretinoin if there are no contraindications.
- Steroid injection therapy—For painful nodules and cysts.

Acne fulminans (Figures 112-9 to 112-11)

- Start with systemic steroids (prednisone 40 to 60 mg/day—approximately 1 mg/kg per day).¹⁶ SOR C
- Systemic steroid treatment rapidly controls the skin lesions and systemic symptoms. The duration of steroid treatment in one Finnish series was 2 to 4 months to avoid relapses.¹⁶ SOR C
- Therapy with isotretinoin, antibiotics, or both was often combined with steroids, but the role of these agents is still uncertain.¹⁶ SOR C
- One British series used oral prednisolone 0.5 to 1 mg/kg daily for 4 to 6 weeks (thereafter slowly reduced to zero).¹⁷ SOR C
- Oral isotretinoin was added to the regimen at the fourth week, initially at 0.5 mg/kg daily and gradually increased to achieve complete clearance.¹⁷ SOR C
- Consider introducing isotretinoin at approximately 4 weeks into the oral prednisone if there are no contraindications. SOR C

Acne conglobata and pyoderma faciale may be treated like acne fulminans but the course of oral prednisone does not need to be as long. SOR C

COMBINATION THERAPIES

- Combination therapy with multiple topical agents can be more effective than single agents.³ SOR B
- Topical retinoids and topical antibiotics are more effective when used in combination than when either are used alone.³ SOR B
- Benzoyl peroxide and topical antibiotics used in combination are effective treatment for acne by helping to minimize antibiotic resistance.³ SOR B
- The adjunctive use of clindamycin/benzoyl peroxide gel with tazarotene cream promotes greater efficacy and may also enhance tolerability.¹⁸
- Combination therapy with topical retinoids and oral antibiotics can be helpful at the start of acne therapy. However, maintenance therapy with combination tazarotene and minocycline therapy showed a trend for greater efficacy but no statistical significance vs. tazarotene alone.¹⁹

FIGURE 112-15 Injection of acne nodules with 2 mg/cc triamcinolone acetonide. (Courtesy of Richard P. Usatine, MD.)

MEDICATION COST

The most affordable medications for acne include topical benzoyl peroxide, erythromycin, clindamycin, and oral tetracycline and doxycycline. The most expensive acne medications are the newest brand-name combination products of existing topical medication. These medications are convenient for those with insurance that covers them (Epiduo contains benzoyl peroxide and adapalene; Ziana contains clindamycin and tretinoin).

NEWER EXPENSIVE MODES OF THERAPY

Intense pulsed light and photodynamic therapy (PDT) use lasers, special lights, and topical chemicals to treat acne.^{20–22} These therapies are very expensive and the data do not suggest that these should be first-line therapies at this time. Light and laser treatments have been shown to be of short-term benefit if patients can afford therapy and tolerate some discomfort. These therapies have not been shown to be better than simple topical treatments.²

One comparative trial demonstrated that PDT was less effective than topical adapalene in the short-term reduction of inflammatory lesions.²

FOLLOW-UP

Isotretinoin requires monthly follow-up visits but other therapies can be monitored every few months at first and then once to twice a year. Keep in mind that many treatments for acne take months to work, so quick follow-up visits may be disappointing.

PATIENT EDUCATION

Adherence with medication regimens is crucial to the success of the therapy. Adequate face washing twice a day is sufficient. Do not scrub the face with abrasive physical or chemical agents. If benzoyl peroxide is not being used as a leave-on product, it can be purchased to use for face washing.

113 ROSACEA

Richard P. Usatine, MD

PATIENT STORY

A 34-year-old woman with extensive papulopustular rosacea (**Figures 113-1 to 113-3**) has a history of easy facial flushing since her teen years. Her face has been persistently redder in the past 5 years and she is bothered by this. She acknowledges that her mom has similar redness in her face and that she is from northern European heritage. In the last 6 months, since her daughter was born, she has developed many “pimples.” Physical examination reveals papules, pustules, and telangiectasias. No comedones are seen. She knows that the sun makes it worse but finds that many sunscreens are irritating to her skin. The patient is started on oral tetracycline daily and 0.75% metronidazole cream to use once daily. She agrees to wear a hat and stay out of the sun during the middle of the day. She will continue to look for a sunscreen she can tolerate. She knows that precipitating factors for her include hot and humid weather, alcohol, hot beverages, and spicy foods. She will do her best to avoid those factors.

INTRODUCTION

Rosacea is an inflammatory condition of the face and eyes that mostly affects adults. Most commonly the face becomes reddened over the cheeks and nose and this is often accompanied by telangiectasias and a papulopustular eruption.

SYNONYMS

Rosacea is also called acne rosacea.

EPIDEMIOLOGY

- Common in fair-skinned people of Celtic and northern European heritage.
- Women are more often affected than men.
- Men are more prone to the extreme forms of hyperplasia, which causes rhinophymatous rosacea (**Figures 113-4 and 113-5**).

ETIOLOGY AND PATHOPHYSIOLOGY

- Although the exact etiology is unknown, the pathophysiology involves nonspecific inflammation followed by dilation around follicles and hyperreactive capillaries. These dilated capillaries become telangiectasias (**Figures 113-6 and 113-7**).
- As rosacea progresses, diffuse hypertrophy of the connective tissue and sebaceous glands ensues (**Figures 113-4 and 113-5**).
- Alcohol may accentuate erythema, but does not cause the disease. Rosacea runs in families.

FIGURE 113-1 Rosacea in a 34-year-old woman showing erythema, papules, and pustules covering much of the face. Note her fair skin and blue eyes from her northern European heritage. (Courtesy of Richard P. Usatine, MD.)

FIGURE 113-2 Close-up of papules and pustules in the same woman. Note the absence of comedones. This is not acne. This is papulopustular rosacea. (Courtesy of Richard P. Usatine, MD.)

- Sun exposure may precipitate an acute rosacea flare, but flare-ups can happen without sun exposure.
- A significant increase in the hair follicle mite *Demodex folliculorum* is sometimes found in rosacea.¹ It is theorized that these mites play a role because they incite an inflammatory or allergic reaction by mechanical blockage of follicles.

RISK FACTORS

Genetics, *Demodex* infestation,¹ sun exposure.

DIAGNOSIS

CLINICAL FEATURES

Rosacea has four stages or subtypes:

1. **Erythematotelangiectatic rosacea** (Figures 113-6 and 113-7)—This stage is characterized by frequent mild to severe flushing with persistent central facial erythema.
2. **Papulopustular rosacea** (Figures 113-1 to 113-3, 113-8 and 113-9)—This is a highly vascular stage that involves longer periods of flushing than the first stage, often lasting from days to weeks. Minute telangiectasias and papules start to form by this stage, and some patients begin having very mild ocular complaints such as ocular grittiness or conjunctivitis. These patients may have many unsightly pustules with severe facial erythema. They are more prone to develop a hordeolum (stye) (see Chapter 13, Hordeolum and Chalazion).
3. **Phymatous or Rhinophymatous rosacea** (Figures 113-4 and 113-5)—Characterized by hyperplasia of the sebaceous glands that form thickened confluent plaques on the nose known as rhinophyma. This hyperplasia can cause significant disfigurement to the forehead, eyelids, chin, and nose. The nasal disfiguration is seen more commonly in men than women. W. C. Fields is famous for his rhinophyma and intake of alcohol. Rhinophyma can occur without any alcohol use, as seen in the patient in Figure 113-5.
4. **Ocular rosacea** (Figures 113-10 to 113-12)—An advanced subtype of rosacea that is characterized by impressive, severe flushing with persistent telangiectasias, papules, and pustules. The patient may complain of watery eyes, a foreign-body sensation, burning, dryness, vision changes, and lid or periocular erythema. The eyelids are most commonly involved with telangiectasias, blepharitis, and recurrent hordeola and chalazia (Figures 113-10 and 113-11). Conjunctivitis may be chronic. Although corneal involvement is least common, it can have the most devastating consequences. Corneal findings may include punctate erosions, corneal infiltrates, and corneal neovascularization. In the most severe cases, blood vessels may grow over the cornea and lead to blindness (Figure 113-12).

TYPICAL DISTRIBUTION

Rosacea occurs on the face, especially on the cheeks and nose. However, the forehead, eyelids, and chin can also be involved (Figure 113-13).

FIGURE 113-3 Close-up showing telangiectasias on the nose and papules around the mouth and chin. (Courtesy of Richard P. Usatine, MD.)

FIGURE 113-4 Rhinophymatous rosacea with hypertrophy of the skin of the nose of a 51-year-old Hispanic man. The patient acknowledges previous heavy alcohol intake. (Courtesy of Richard P. Usatine, MD.)

LABORATORY STUDIES

Not needed when the clinical picture is clear. If you are considering lupus or sarcoid, an antinuclear antibody (ANA), chest X-ray, or punch biopsy may be needed.

DIFFERENTIAL DIAGNOSIS

- Acne—The age of onset for rosacea tends to be 30 to 50 years, much later than the onset for acne vulgaris. Comedones are prominent in most cases of acne and generally absent in rosacea (see Chapter 112, Acne Vulgaris).
- Sarcoidosis on the face is much less common than rosacea, but the inflamed plaques can be red and resemble the inflammation of rosacea (see Chapter 175, Sarcoidosis).
- Seborrheic dermatitis tends to produce scale, whereas rosacea does not. Although both cause central facial erythema, papules and telangiectasias are present in rosacea and are not part of seborrheic dermatitis (see Chapter 151, Seborrheic Dermatitis).
- Systemic lupus erythematosus (SLE) can be scarring, does not usually produce papules or pustules, and it spares the nasolabial folds and nose (see Chapter 180, Lupus: Systemic and Cutaneous). The patient in **Figure 113-13** has a butterfly distribution of her rosacea, but her right nasolabial fold is involved along with her chin.

The following three diagnoses were once considered variants of rosacea but a recent classification system identified these as separate entities:²

- Rosacea fulminans (known as pyoderma faciale) is characterized by the sudden appearance of papules, pustules, and nodules, along with fluctuating and draining sinuses that may be interconnecting. The condition appears primarily in women in their 20s, and intense redness and edema also may be prominent (**Figure 113-14**).²
- Steroid-induced acneiform eruption is not a variant of rosacea and can occur as an inflammatory response in any patient during or after chronic corticosteroid use. The same inflammatory response may also occur in patients with rosacea (**Figure 113-15**).
- Perioral dermatitis without rosacea symptoms should not be classified as a variant of rosacea. Perioral dermatitis is characterized by microvesicles, scaling, and peeling around the mouth (**Figure 113-16**).

MANAGEMENT

- A Cochrane Database systematic review examined the efficacy of rosacea interventions.³ Oral doxycycline appeared to be significantly more effective than placebo and there was no statistically significant difference in effectiveness between the 100-mg and 40-mg doses.² **SOR A** They found some evidence to support the effectiveness of topical metronidazole (0.75% or 1%), azelaic acid (15% or 20%) for the treatment of moderate to severe rosacea.² **SOR A** Cyclosporine ophthalmic emulsion was significantly more effective than artificial tears for treating ocular rosacea (for all outcomes).² **SOR A**
- When there are a limited number of papules and pustules, start with topical metronidazole (0.75% or 1%) or topical azelaic acid (15% or 20%).³

FIGURE 113-5 Rhinophymatous rosacea in an older man who does not drink alcohol. Although this is often called a W. C. Field nose, it is not necessarily related to heavy alcohol use. (Courtesy of Richard P. Usatine, MD.)

FIGURE 113-6 Erythematotelangiectatic subtype of rosacea in a middle-aged Hispanic woman. (Courtesy of Richard P. Usatine, MD.)

- There are no substantial differences between topical metronidazole of 0.75% and 1%, or between once daily and twice daily regimens.⁴ Metronidazole cream, gel, and lotion have similar efficacies as well.⁴
- Azelaic acid in a 15% gel applied bid appeared to offer some modest benefits over 0.75% metronidazole gel in a manufacturer-sponsored study.⁴ Azelaic acid was not as well tolerated, so both medications are reasonable options with the choice depending on patient preference and tolerance.³ **SOR B** One study found that once-daily azelaic acid 15% gel was as effective as twice-daily application, which can translate into a significant cost saving.⁵
- If the skin lesions are more extensive, oral antibiotics, such as doxycycline (40 mg or 100 mg daily) is recommended.² **SOR A** When attempting to avoid the photosensitivity side effects of doxycycline it is reasonable to prescribe oral tetracycline (250 mg to 500 mg daily) or oral metronidazole (250 mg to 500 mg daily). **SOR C**
- Patients who are started on oral antibiotics alone and improve may be switched to topical agents such as metronidazole or azelaic acid for maintenance.
- The *Demodex* mite may be one causative agent in rosacea. One study found permethrin 5% cream to be as effective as metronidazole 0.75% gel and superior to placebo in the treatment of rosacea.⁵ **SOR B**
- Severe papulopustular disease refractory to antibiotics and topical treatments can be treated with oral isotretinoin at a low dose of 0.3 mg/kg per day.⁶ **SOR B**
- Simple electrosurgery or laser without anesthesia can be used to treat the telangiectasias associated with rosacea. **SOR C**
- Rhinophyma can be excised with radiofrequency electrosurgery or laser. Isotretinoin is also used to treat rhinophyma.⁶ **SOR B**
- Traditional therapies for mild ocular rosacea include oral tetracyclines, lid hygiene, and warm compresses.¹ **SOR C** Topical ophthalmic cyclosporine 0.05% (Restasis) is more effective than artificial tears for the treatment of rosacea-associated lid and corneal changes.⁷ **SOR B** Ocular rosacea that involves the cornea should be immediately referred to an ophthalmologist to prevent blindness (Figure 113-12).

FOLLOW-UP

Follow-up can be in 1 to 3 months as needed.

PATIENT EDUCATION

Sun protection, including use of a hat and daily application of sunscreen, should be emphasized. Choose a sunscreen that is nonirritating and protects against UVA and UVB rays. Advise patients to keep a diary to identify and avoid precipitating factors such as hot and humid weather, alcohol, hot beverages, spicy foods, and large hot meals.

114 PSEUDOFOLLICULITIS AND ACNE KELOIDALIS NUCHAE

E.J. Mayeaux, Jr., MD

PATIENT STORY

A 17-year-old young African American man comes to the office because, for the past 2 years, he has been bothered by the uncomfortable bumps on the back of his neck (**Figure 114-1**). He is an athletic young man, more than 6 feet tall, and likes to keep his hair short for his sports. He notices the bumps get irritated and larger when he shaves his hair. He also has bumps on his face that get worse when he shaves his face (**Figure 114-2**). He is diagnosed with pseudofolliculitis barbae and acne keloidalis nuchae. His treatment consisted of patient education and twice-daily tretinoin cream and 0.1% triamcinolone cream to the neck area and nightly tretinoin cream to the beard area. He was told he could use 1% hydrocortisone cream on his face as needed. It was suggested that he minimize shaving, if possible.

INTRODUCTION

Pseudofolliculitis is a common skin condition affecting the hair-bearing areas of the body that are shaved (**Figures 114-2 to 114-4**). Potential complications include postinflammatory hyperpigmentation, bacterial superinfection, and keloid formation.

SYNONYMS

- Pseudofolliculitis—Razor bumps, shave bumps.
- Acne keloidalis nuchae—Folliculitis keloidalis.

EPIDEMIOLOGY

- Pseudofolliculitis is most common in black men, with at least 50% of black men who shave being prone to the condition.¹ In the beard area it is called *pseudofolliculitis barbae*, and when it occurs after pubic hair is shaved, it is referred to as *pseudofolliculitis pubis*. It may also occur in the neck area.
- Acne keloidalis nuchae occurs most often in black men but can be seen in all ethnicities (**Figures 114-3 and 114-5**). The lesions are often painful and cosmetically disfiguring.
- Both conditions are seen in women but far less often than in men (**Figure 114-6**).

ETIOLOGY AND PATHOPHYSIOLOGY

- Pseudofolliculitis develops when, after shaving, the free end of tightly coiled hair reenters the skin, causing a foreign-body–like

FIGURE 114-1 Acne keloidalis nuchae in a 17-year-old African American man. (Courtesy of Richard P. Usatine, MD.)

FIGURE 114-2 Pseudofolliculitis barbae along the jawline and neck in the patient in Figure 114-1. (Courtesy of Richard P. Usatine, MD.)

inflammatory reaction. Shaving produces a sharp free end below the skin surface. Tightly curled hair has a greater tendency for the tip to pierce the surface of the skin and form ingrown hairs. This explains the relative predominance of this condition in patients of African ethnicity. The hair eventually forms a loop and if the embedded tip is pulled out there may be spontaneous resolution of symptoms.

- The exact cause of acne keloidalis is uncertain. It often develops in areas of pseudofolliculitis or folliculitis. It may be associated with haircuts where the posterior hairline is shaved with a razor and with tightly curved hair shafts. Other possible etiologies include irritation from shirt collars, chronic bacterial infections, and an autoimmune process. It is a form of primary scarring alopecia.² As such, multiple hairs can be seen growing from single follicle (hair tufts) in the midst of the keloidal scarring (**Figure 114-7**).

RISK FACTORS

- Pseudofolliculitis:
 - African ethnicity.
 - Curly hair.
- Acne keloidalis nuchae:
 - Shaving the hair on the neck.
 - Pseudofolliculitis.

DIAGNOSIS

CLINICAL FEATURES

- The diagnosis of pseudofolliculitis is based upon clinical appearance. A piece of hair often may be identified protruding from a lesion. Inflammation results in the formation of firm, skin-colored, erythematous or hyperpigmented papules that occur after shaving (**Figures 114-2 to 114-4**). Pustules may develop secondarily. The severity varies from a few papules or pustules to hundreds of lesions.
- Patients with acne keloidalis initially develop a folliculitis or pseudofolliculitis, which heals with keloid-like lesions, sometimes with discharging sinuses. It starts after puberty as 2- to 4-mm firm, follicular papules (**Figure 114-1**). More papules appear and enlarge over time (**Figure 114-5**). Papules may coalesce to form keloid-like plaques, which are usually arranged in a band-like distribution along the posterior part of the hairline (**Figures 114-7 and 114-8**).

TYPICAL DISTRIBUTION

- Pseudofolliculitis affects the hair-bearing areas of the body that are shaved, especially the face, neck, and pubic area (**Figures 114-2 to 114-4**).
- Acne keloidalis occurs on the occipital scalp and the posterior part of the neck (**Figures 114-1, 114-5, and 114-7**).

BIOPSY

- Histologic evaluation of a biopsy may confirm either diagnosis but is usually not necessary.

FIGURE 114-3 Pseudofolliculitis barbae in a Dominican man. Note the active pustules on the neck. (Courtesy of Richard P. Usatine, MD.)

FIGURE 114-4 Pseudofolliculitis barbae on the face of a 28-year-old African man who works providing aid to Darfur refugees. The painful nodules become worse every time he shaves. (Courtesy of Richard P. Usatine, MD.)

FIGURE 114-5 Acne keloidalis with multiple firm keloidal papules in a Hispanic man who prefers to keep his hair short. (Courtesy of Richard P. Usatine, MD.)

DIFFERENTIAL DIAGNOSIS

- True folliculitis, which is an acute pustular infection of a hair follicle with more localized inflammation (see Chapter 117, Folliculitis).
- Impetigo, which presents with yellowish pustules or bullae that rupture and develop honey crusts, sometimes with adenopathy (see Chapter 116, Impetigo).
- Acne vulgaris, which presents with comedones and pustules usually including the forehead (see Chapter 112, Acne Vulgaris).

MANAGEMENT

NONPHARMACOLOGIC

- Avoid close shaving, avoid all shaving, or permanently remove hair.³ Some occupations, however, such as the military and law enforcement, require facial shaving. Occasionally, a doctor's note will allow these men to go without shaving. In mild cases, shaving should be discontinued for a month. The beard can be coarsely trimmed with scissors or electric clippers during this time. Shaving should not resume until all inflammatory lesions have resolved. Warm Burow solution compresses may be applied to the lesions for 10 minutes, 2 times per day. Instruct the patient to search for ingrown hairs each day using a magnifying mirror and release them gently using a sterilized needle or tweezers. The hairs should not be plucked as this may cause recurrence of symptoms with hair regrowth (Figure 114-6). **SOR C**
- Chemical depilatories (Ali, Royal Crown, Magic Shave, and others) cause fewer symptoms than shaving.⁴ **SOR B** However, these creams can cause severe irritation, so testing a small amount on the forearm is important. They work by breaking the disulfide bonds in hair, which results in the hair being bluntly broken at the follicular opening instead of sharply cut below the surface. They should be used every second or third day to avoid skin irritation, although this can be controlled with hydrocortisone cream. Barium sulfide 2% powder depilatories can be made into a paste with water, applied to the beard, and removed after 3 to 5 minutes. Calcium thioglycolate preparations are left on 10 to 15 minutes, but the fragrances can cause an allergic reaction and chemical burns can result if it is left for too long.
- People who have acne keloidalis nuchae should avoid anything that causes folliculitis or pseudofolliculitis, such as getting their neck or hairline shaved with a razor.

MEDICATIONS

- Topical eflornithine HCL 13.9% cream (Vaniqa; by prescription only) may be used to inhibit hair growth. It decreases the rate of hair growth and may make the hair finer and lighter. Unfortunately, this medication is expensive and requires daily application for continued efficacy. **SOR C**
- Twice-daily treatment with a class 2 or 3 corticosteroid may be sufficient to shrink pseudofolliculitis lesions and relieve symptoms (see Appendix 2: Topical and Intralesional Corticosteroids). **SOR C**
- When pustules, crust formation, or drainage is present, use topical clindamycin or erythromycin. Unresponsive patients may be changed to a systemic antibiotic. **SOR C**

FIGURE 114-6 Pseudofolliculitis barbae in a black woman with hirsutism. The scarring is related to plucking and shaving the hairs on the neck. (Courtesy of Richard P. Usatine, MD.)

FIGURE 114-7 Acne keloidalis nuchae with large keloidal mass in a Hispanic man. Note multiple hairs can be seen growing from single follicles (hair tufts). Surgery is the only treatment that can remove this keloidal mass. (Courtesy of Richard P. Usatine, MD.)

FIGURE 114-8 Acne keloidalis nuchae after injection with intralesional triamcinolone. Although the keloid is smaller and softer, some hypopigmentation has occurred. (Courtesy of Richard P. Usatine, MD.)

- Topical erythromycin, clindamycin, and combination clindamycin-benzoyl peroxide (BenzaClin, Duac) and erythromycin-benzoyl peroxide (Benzamycin) may be used once or twice daily.⁵ **SOR B**
- Oral doxycycline 100 mg bid, tetracycline 500 mg bid, or erythromycin 500 mg bid may be used for patients with more severe secondary inflammation. **SOR C**
- Tretinoin cream, 0.025%, may be useful in patients with mild disease, but is rarely helpful in moderate to severe cases.⁶ It is applied nightly for a week then reduced to every second or third night. Tretinoin may be used in conjunction with a mid-potency topical corticosteroid applied each morning. The mechanism of action is thought to be by relieving hyperkeratosis and “toughening” the skin. Topical combination cream (tretinoin 0.05%, fluocinolone acetonide 0.01%, and hydroquinone 4%) (Tri-Luma) adds an additional postinflammatory hyperpigmentation treatment. **SOR C**
- Intralesional steroid injections (10 to 20 mg/mL) may be used to soften and shrink keloids. Warn patients that this therapy may cause hypopigmentation (**Figure 114-8**). **SOR C**

SURGICAL

- The only definitive cure for pseudofolliculitis is permanent hair removal. Electrolysis is expensive, painful, and sometimes unsuccessful. Laser hair removal is fairly successful for treating pseudofolliculitis.⁷ **SOR B** Diode laser (810 nm) treatments have been proven safe and effective in patients with skin phototypes I to IV.⁸
- Excision of acne keloidalis lesions may be attempted. Recalcitrant keloidal lesions may be treated with removing individual papules with a small punch, or large keloids (**Figure 114-9**) with an elliptical excision closed with sutures. After removal, the wound edges should be injected with a mixture of equal amount of triamcinolone acetonide 40 mg/mL and sterile saline. Remove the sutures in 1 to 2 weeks and inject the edges every month with the above mixture for 3 to 4 times. **SOR C** Excision should extend into the subcutaneous tissue and the wound edges can be injected with 10 to 40 mg/mL of triamcinolone acetonide and be reapproximated. **SOR C** Recurrence is common, especially with shallow excisions or not treating with steroids.
- Other therapies that may be considered are laser therapy (carbon dioxide or Nd:YAG [neodymium:yttrium-aluminum-garnet]) followed by intralesional triamcinolone injections or cryotherapy for two 20-second bursts that are allowed to thaw and are then applied again a minute later. These methods may produce more pain and hypopigmentation. **SOR C**

PREVENTION

- Termination of shaving prevents the development of pseudofolliculitis.

PROGNOSIS

- No specific cure exists. If the patient is able to stop shaving, the problem usually disappears (except for any scar formation).

FIGURE 114-9 Hypertrophic scarring after the excision of acne keloidalis nuchae. (Courtesy of Richard P. Usatine, MD.)

FOLLOW-UP

- Instruct patients to return if any complications occur. Otherwise have them return for possible initiation of intralesional steroid injections or topical steroid/retinoic acid therapy once the area has healed.

PATIENT EDUCATION

- For those who must shave, have the patient clip hairs no shorter than needed for maintenance. Use fine scissors or facial hair clippers if possible. When shaving, have the patient rinse with warm tap water for several minutes, use generous amounts of a highly lubricating shaving gel, and allow it to soften the skin for 5 to 10 minutes before shaving. The patient should always use sharp razors and shave in the direction of hair growth. Specialized guarded razors (e.g., PFB Bump Fighter) are available in pharmacies and by mail order. After shaving rinse the face with tap water, and then apply cold water compresses.
- With acne keloidalis, instruct males who play football to make sure their helmets fit properly and do not cause irritation on the posterior part of the scalp. They should avoid having the posterior part of the hairline shaved with a razor as part of a haircut, and discontinue wearing garments that rub or irritate the posterior parts of the scalp and the neck.

115 HIDRADENITIS SUPPURATIVA

Richard P. Usatine, MD

PATIENT STORY

A 25-year-old woman presents with new tender lesions in her axilla (**Figure 115-1**). She admits to years of similar outbreaks in both axilla and occasional painful bumps in the groin. She states that it is painful to have them opened and just wants to get some relief without surgery. We elected to inject the nodules with triamcinolone and start the patient on doxycycline 100 mg twice daily. Smoking cessation was emphasized and the patient agreed to start on a nicotine patch that evening. She had relief within 24 hours from the steroid injection.

INTRODUCTION

Hidradenitis suppurativa (HS) is an inflammatory disease of the pilosebaceous unit in the apocrine gland-bearing skin. HS is most common in the axilla and inguinal area, but may be found in the inframammary area as well. It produces painful inflammatory nodules, cysts, and sinus tracks with mucopurulent discharge and progressive scarring.

SYNONYMS

It is called acne inversa because it involves intertriginous areas and not the regions affected by acne (similar to inverse psoriasis).

EPIDEMIOLOGY

- Occurs after puberty in approximately 1% of the population.¹
- Incidence is higher in females, in the range of 4:1 to 5:1. Flare-ups may be associated with menses.¹

ETIOLOGY AND PATHOPHYSIOLOGY

- Disorder of the terminal follicular epithelium in the apocrine gland-bearing skin.¹
- Starts with occlusion of hair follicles that lead to occlusion of surrounding apocrine glands.
- Chronic relapsing inflammation with mucopurulent discharge (**Figures 115-2 to 115-7**).
- Can lead to sinus tracts, draining fistulas and progressive scarring (**Figures 115-2 to 115-7**).

FIGURE 115-1 Mild hidradenitis suppurativa in the axilla of a young woman. She has a history of recurrent lesions in her axilla. (Courtesy of Richard P. Usatine, MD.)

RISK FACTORS

Obesity, smoking, and tight-fitting clothing.

DIAGNOSIS

CLINICAL FEATURES

- Most common presentation is painful, tender, firm, nodular lesions in axillae (**Figures 115-1 to 115-3**).
- Nodules may open and drain pus spontaneously and heal slowly, with or without drainage, over 10 to 30 days.¹
- Nodules may recur several times yearly, or in severe cases new lesions form as old ones heal.
- Surrounding cellulitis may be present and require systemic antibiotic treatment.
- Chronic recurrences result in thickened sinus tracts, which may become draining fistulas (**Figures 115-3 to 115-7**).
- HS can cause disabling pain, diminished range of motion, and social isolation (**Figure 115-5**).

TYPICAL DISTRIBUTION

- Axillary, inguinal, periareolar, intermammary zones, pubic area, infraumbilical midline, gluteal folds, top of the anterior thighs, and the perianal region.¹

LABORATORY STUDIES

Culture of purulence is likely to yield staphylococci and streptococci and is usually unnecessary to determine treatment. Culture may be useful if you suspect methicillin-resistant *Staphylococcus aureus*.

DIFFERENTIAL DIAGNOSIS

- Bacterial infections, including folliculitis, carbuncles, furuncles, abscess, and cellulitis, may resemble HS but are less likely to be recurrent in the intertriginous areas.
- Epidermal cysts in the intertriginous regions may resemble HS. These cysts contain malodorous keratin contents.
- Granuloma inguinale and lymphogranuloma venereum are sexually transmitted infections that can produce inguinal ulcers and adenopathy that could be mistaken for HS.

MANAGEMENT

- Lifestyle changes are recommended, including weight loss if obesity is present. **SOR C**
- Smoking is a risk factor for HS and cessation is highly recommended for many reasons.¹ See **SOR B** for HS and **SOR A** for other health reasons.
- Frequent bathing and wearing loose-fitting clothing may help.

FIGURE 115-2 Moderate HS in a young woman. The lesions are deeper and there have been some chronic changes with scarring and fibrosis from previous lesions. (Courtesy of Richard P. Usatine, MD.)

FIGURE 115-3 A 33-year-old Hispanic woman with sinus tracts, draining fistulas, and scarring secondary to her chronic HS. Note the mucopurulent discharge. (Courtesy of Richard P. Usatine, MD.)

Medical treatment is similar to acne treatment:

- Oral antibiotics are used in acute and chronic treatment. Oral tetracyclines, clindamycin, rifampin, and dapsones have been touted as beneficial. If there is methicillin-resistant *S. aureus* present, trimethoprim/sulfamethoxazole or clindamycin should be used.
- Tetracycline 500 mg bid and doxycycline 100 mg bid can be used acutely and to prevent new lesions in the mildest of cases. Many patients do not find these antibiotics to be of great help. **SOR C**
- Topical clindamycin bid may be used in the mildest of cases. In one randomized controlled trial (RCT), systemic therapy with tetracyclines did not show better results than topical therapy with clindamycin.¹ **SOR B**
 - Combination of systemic clindamycin (300 mg twice daily) and rifampin (600 mg daily) is recommended for patients with more severe HS.^{2,3} In a series of 116 patients, parameters of severity improved, as did the quality-of-life score.² In another study, 28 of 34 patients (82%) experienced at least partial improvement, and 16 (47%) showed a total remission.³ The maximum effect of treatment appeared within 10 weeks. Following total remission, 8 of 13 (61.5%) patients experienced a relapse after a mean period of 5 months. Nonresponders were predominantly patients with severe disease. The most frequent side effect is diarrhea.^{2,3}
 - Oral dapsones may be considered in milder cases. In one study, only 38% of patients experienced improvement.⁴ **SOR B** Rapid recurrence after stopping treatment suggests that antiinflammatory effects may predominate over antimicrobial effects. The total effect appears to be smaller than that reported with combination therapy using clindamycin and rifampicin.
- Isotretinoin can reduce the severity of attacks in some patients but is not a reliable cure for HS.⁵ **SOR C**
- Acitretin can be an effective treatment for refractory HS. In one study, all 12 patients achieved remission and experienced a significant decrease in pain. Long-lasting improvement was observed in 9 patients, with no recurrence of lesions after 6 months (n = 1), 1 year (n = 3), more than 2 years (n = 2), more than 3 years (n = 2), and more than 4 years (n = 1).⁵ **SOR B**
- Antitumor necrosis factor (TNF) agents are being studied for severe, recalcitrant HS (**Figure 115-8**). In one series, infliximab therapy (weight based) was shown to be effective and well tolerated in 6 of 7 patients with HS who were resistant to previous therapy.⁶ This was in agreement with preexisting literature showing that 52 of 60 patients (87%) were improved after infliximab therapy.⁶ **SOR B** Adalimumab helps in the short-term, but no long-term curative effect was uniformly seen.⁷
- Intense pulsed light (IPL) with laser may be worth considering for patients who can afford the cost and time for treatment. In one study of 18 patients who were randomized to treatment of one axilla, groin, or inframammary area with IPL 2 times per week for 4 weeks, there was a significant improvement in the mean examination score, which was maintained at 12 months. Patients reported high levels of satisfaction with the IPL treatment.⁸ **SOR B**

Surgical treatments include the following:

- Intralesional steroids with 5 to 10 mg/mL of triamcinolone may help to decrease inflammation and pain within 24 to 48 hours. **SOR C**

FIGURE 115-4 Longstanding painful severe HS between the breasts of a 45-year-old woman. (Courtesy of Richard P. Usatine, MD.)

FIGURE 115-5 Severe disabling HS in a 34-year-old white man who is morbidly obese. He finds it painful to walk. (Courtesy of Richard P. Usatine, MD.)

- Incision and drainage of acute lesions are suggested for the large fluctuant abscesses that can occur in HS. Although this may give some relief of the pressure, the surgical treatment and repacking of the wound is painful, and there is no evidence that it speeds healing. **SOR C**
- Lancing small nodules is more painful than helpful and is not recommended.
- Surgical excision of affected area with or without skin grafting is used for recalcitrant disabling disease and should be individualized based on the stage and location of the disease.⁹ **SOR B** One surgical group has been using a medial thigh lift for immediate defect closure after radical excision of localized inguinal hidradenitis.¹⁰

FOLLOW-UP

If there is cellulitis or a large abscess was drained, follow-up should be within days. Chronic relapsing disease can ultimately be managed with appointments every 3 to 6 months depending upon the treatment and its success.

PATIENT EDUCATION

Smoking cessation, weight loss if overweight, and avoidance of tight-fitting clothes.

SECTION 3 BACTERIAL

116 IMPETIGO

Richard P. Usatine, MD

PATIENT STORIES

A young woman presented to the office with a 3-day history of an uncomfortable rash on her lip and chin (**Figure 116-1**). She denied any trauma or previous history of oral herpes. This case of impetigo resolved quickly with oral cephalexin.

An 11-year-old-child presented with a 5-day history of a skin lesion that started after a hiking trip (**Figure 116-2**). This episode of bullous impetigo was found to be secondary to methicillin-resistant *Staphylococcus aureus* (MRSA). The lesion was rapidly progressive and was developing a surrounding cellulitis. She was admitted to a hospital and treated with intravenous clindamycin with good results.¹

INTRODUCTION

Impetigo is the most superficial of bacterial skin infections. It causes honey crusts, bullae, and erosions.

EPIDEMIOLOGY

- Most frequent in children ages 2 to 6 years, but it can be seen in patients of any age.
- Common among homeless people living on the streets.
 - Seen often in third world countries in persons living without easy access to clean water and soap.
- Contagious and can be spread within a household.

ETIOLOGY AND PATHOPHYSIOLOGY

- Impetigo is caused by *S. aureus* and/or group A β -hemolytic *Streptococcus* (GABHS).
- Bullous impetigo is almost always caused by *S. aureus* and is less common than the typical crusted impetigo.
- Impetigo may occur after minor skin injury, such as an insect bite, abrasion, or dermatitis.

DIAGNOSIS

CLINICAL FEATURES

- Vesicles, pustules, honey-colored (**Figure 116-1**), brown or dark crusts, erythematous erosions (**Figure 116-3**), ulcers in ecthyma (**Figure 116-4**), bullae in bullous impetigo (**Figures 116-5 to 116-7**).

FIGURE 116-1 Typical honey-cruled plaque on the lip of an adult with impetigo. (Courtesy of Richard P. Usatine, MD.)

FIGURE 116-2 Bullous impetigo secondary to methicillin-resistant *Staphylococcus aureus* (MRSA) on the leg of an 11-year-old child. Note the surrounding cellulitis. (With permission from Studdiford J, Stonehouse A. Bullous eruption on the posterior thigh 1. *J Fam Pract.* 2005;54:1041-1044. Reproduced with permission from Frontline Medical Communications.)

TYPICAL DISTRIBUTION

- Face (**Figures 116-1, 116-4 to 116-6, and 116-8**) is most common, followed by hands, legs (**Figures 116-2 and 116-9**), trunk, and buttocks.

CULTURE

- Culture should be considered in severe cases because of the rising incidence of MRSA-causing impetigo.

DIFFERENTIAL DIAGNOSIS

Many of the conditions below can become impetigo after being secondarily infected (**Figures 116-10 and 116-11**) with bacteria. This process is called impetiginization.

- Atopic dermatitis—A common inflammatory skin disorder characterized by itching and inflamed skin. It can become secondarily infected with bacteria (**Figure 116-11**) (see Chapter 145, Atopic Dermatitis).
- Herpes simplex virus infection anywhere on the skin or mucous membranes can become secondarily infected (see Chapter 129, Herpes Simplex).
- Eczema herpeticum is eczema superinfected with herpes rather than bacteria (**Figure 145-4**).
- Scabies—Pruritic contagious disease caused by a mite that burrows in skin (see Chapter 143, Scabies).
- Folliculitis—Inflammation and/or infection of hair follicles that may be bacterial (see Chapter 117, Folliculitis).
- Tinea corporis—A cutaneous fungal infection caused by dermatophytes, frequently with ring-like scale (see Chapter 138, Tinea Corporis).
- Pemphigus vulgaris—Somewhat rare bullous autoimmune condition with flaccid vesicles and bullae that rupture easily, affecting people between 40 and 60 years of age (see Chapter 185, Pemphigus).
- Bullous pemphigoid—An autoimmune condition with multiple tense bullae that primarily affects people older than 60 years of age (see Chapter 184, Bullous Pemphigoid).
- Acute allergic contact dermatitis—Dermatitis from direct cutaneous exposure to allergens such as poison ivy. Acute lesions are erythematous papules and vesicles in a linear pattern (see Chapter 146, Contact Dermatitis).
- Insect bites—Scratched, open lesions can become secondarily infected with bacteria (impetiginized) (**Figure 116-9**).
- Second-degree burn or sunburn—The blisters when opened leave the skin susceptible to secondary infection (**Figure 116-10**).
- Staphylococcal scalded skin syndrome—Life-threatening syndrome of acute exfoliation of the skin caused by an exotoxin from a staphylococcal infection. This condition is seen almost entirely in infants and young children (**Figure 116-12**).

MANAGEMENT

- There is good evidence that topical mupirocin is equally or more effective than oral treatment for people with limited impetigo.
SOR **A** Mupirocin also covers MRSA.²

FIGURE 116-3 Widespread impetigo with honey-crusted erythematous lesions on the back of a 7-year-old child. (Courtesy of Richard P. Usatine, MD.)

FIGURE 116-4 Impetigo on the face and hand of a homeless man. Note the ecthyma (ulcerated impetigo) on the dorsum of the hand. (Courtesy of Richard P. Usatine, MD.)

FIGURE 116-5 Bullous impetigo around the mouth of a young boy that progressed to desquamation of the skin on his hands and feet. (Courtesy of Richard P. Usatine, MD.)

FIGURE 116-6 Bullous impetigo on the face of a 14-year-old girl. Methicillin-resistant *Staphylococcus aureus* was cultured from the impetigo. (Courtesy of Richard P. Usatine, MD.)

FIGURE 116-8 Impetigo on the face and neck of an infant. (Courtesy of Richard P. Usatine, MD.)

FIGURE 116-7 Bullous impetigo on the abdomen of an 8-year-old boy. (Courtesy of Richard P. Usatine, MD.)

FIGURE 116-9 Impetigo secondary to flea bites on the legs of a young girl. (Courtesy of Richard P. Usatine, MD. Previously published in the *Western Journal of Medicine*.)

- Extensive impetigo could be treated for 7 days with antibiotics that cover GABHS and *S. aureus*, such as cephalexin or dicloxacillin.³ **SOR A**
- Community-acquired MRSA can present as bullous impetigo in children (**Figures 116-2 and 116-6**) or adults.
- If you suspect MRSA, culture the lesions and start one of the following oral antibiotics: trimethoprim-sulfamethoxazole, clindamycin, tetracycline, or doxycycline.⁴ **SOR A** Trimethoprim-sulfamethoxazole achieved 100% clearance in the treatment of impetigo in children cultured with MRSA and GABHS in one small randomized controlled trial (RCT).⁶
- If there are recurrent MRSA infections, one might choose to prescribe intranasal mupirocin ointment and chlorhexidine bathing to decrease MRSA colonization.⁵ **SOR B**

PREVENTION

Practice good hygiene with soap and water. Avoid sharing towels and wash clothes.

FOLLOW-UP

Arrange follow-up based on severity of case and the age and immune status of the patient.

PATIENT EDUCATION

Discuss hygiene issues and how to avoid spread within the household or other living situations such as homeless shelters.

117 FOLLICULITIS

Richard P. Usatine, MD
Khalilah Hunter-Anderson, MD

PATIENT STORY

A 42-year-old woman is seen for multiple papules and pustules on her back (**Figure 117-1**). Further questioning demonstrates that she was in a friend's hot tub twice over the previous weekend. The outbreak on her back started after she went into the hot tub the second time. This is a case of *Pseudomonas* folliculitis or "hot tub" folliculitis. The patient avoided this hot tub and the folliculitis disappeared spontaneously. Another option is to treat with an oral fluoroquinolone that covers *Pseudomonas*.

INTRODUCTION

Folliculitis is an inflammation of hair follicles usually from an infectious etiology. Multiple species of bacteria have been implicated, as well as fungal organisms.

EPIDEMIOLOGY

- Folliculitis is a cutaneous disorder that affects all age groups and races, and both genders.
- It can be infectious or noninfectious. It is most commonly of bacterial origin (**Figures 117-2** and **117-3**).
- Pseudofolliculitis or sycosis barbae is most frequently seen in men of color and made worse by shaving (**Figure 117-4**).¹
- Acne keloidalis nuchae or keloidal folliculitis is commonly seen in black patients, but can be seen in patients of any ethnic background (**Figures 117-5** and **117-6**).²
- Eosinophilic folliculitis is described in patients with HIV infection (**Figure 117-7**).
- Methicillin-resistant *Staphylococcus aureus* (MRSA) can pose a challenge to the treatment of folliculitis (**Figure 117-8**).

ETIOLOGY AND PATHOPHYSIOLOGY

- Folliculitis is an infection of the hair follicle and can be superficial, in which it is confined to the upper hair follicle, or deep, in which inflammation spans the entire depth of the follicle.
- Infection can be of bacterial, viral, or fungal origin. *S. aureus* is by far the most common bacterial causative agent.
- The noninfectious form of folliculitis is often seen in adolescents and young adults who wear tight-fitting clothes. Folliculitis can also be caused by chemical irritants or physical injury.
- Topical steroid use, ointments, lotions, or makeup can swell the opening to the pilosebaceous unit and cause folliculitis.

FIGURE 117-2 Close-up of bacterial folliculitis showing hairs coming through pustules. (Courtesy of Richard P. Usatine, MD.)

- Bacterial folliculitis or *Staphylococcus* folliculitis typically presents as infected pustules most prominent on the face, buttocks, trunk, or extremities. It can progress to a deeper infection with the development of furuncles or boils (**Figure 117-9**). Infection can occur as a result of mechanical injury or via local spread from nearby infected wounds. An area of desquamation is frequently seen surrounding infected pustules in *S. aureus* folliculitis.¹⁻³
- Parasitic folliculitis usually occurs as a result of mite infestation (*Demodex*). These are usually seen on the face, nose, and back and typically cause an eosinophilic pustular-like folliculitis.¹
- Folliculitis decalvans is a chronic form of folliculitis involving the scalp, leading to hair loss or alopecia (**Figure 117-10**). Staphylococci infection is the usual causative agent, but there also has been a suggested genetic component to this condition.¹ It is also called tufted folliculitis because some of the hair follicles will have many hairs growing from them simultaneously (**Figure 117-11**) (see Chapter 189, Scarring Alopecia).
- Acne keloidalis nuchae is a chronic form of folliculitis found on the posterior neck that can be extensive and lead to keloidal tissue and alopecia.¹⁻³ Although it is often thought to occur almost exclusively in black men, it can be seen in men of all ethnic backgrounds and occasionally in women (**Figures 117-5 and 117-6**) (see Chapter 114, Pseudofolliculitis and Acne Keloidalis Nuchae).
- Fungal folliculitis is epidermal fungal infections that are seen frequently. Tinea capitis infections are a form of dermatophytic folliculitis (see Chapter 137, Tinea Capitis). *Pityrosporum* folliculitis is caused by yeast infection (*Malassezia* species) and is seen in a similar distribution as bacterial folliculitis on the back, chest, and shoulders (**Figure 117-12**) (see Chapter 141, Tinea Versicolor). Candidal infection is less common and is usually seen in individuals who are immunosuppressed, present in hairy areas that are moist, and unlike most cases of folliculitis, may present with systemic signs and symptoms.^{1,4}
- *Pseudomonas* folliculitis or “hot tub” folliculitis is usually a self-limited infection that follows exposure to water or objects that are contaminated with *Pseudomonas aeruginosa* (**Figure 117-1**). This occurs when hot tubs are inadequately chlorinated or brominated. This also occurs when loofah sponges or other items used for bathing become a host for pseudomonal growth. Onset of symptoms is usually within 6 to 72 hours after exposure, with the complete resolution of symptoms in a couple of days, provided that the individual avoids further exposure.⁴
- Gram-negative folliculitis is an infection with Gram-negative bacteria that most typically occurs in individuals who have been on long-term antibiotic therapy, usually those taking oral antibiotics for acne. The most frequently encountered infective agents include *Klebsiella*, *Escherichia coli*, *Enterobacter*, and *Proteus*.⁵
- Pseudofolliculitis barbae (razor bumps) is most commonly seen in black males who shave. Papules develop when the sharp edge of the hair shaft reenters the skin (ingrown hairs), and is seen on the cheeks and neck as a result of curled ingrown hair.² It can also occur in women with hirsutism who shave or pluck their hairs (**Figure 117-4**) (see Chapter 114, Pseudofolliculitis and Acne Keloidalis Nuchae).⁶
- Viral folliculitis seen is primarily caused by herpes simplex virus and molluscum contagiosum.⁴ Herpetic folliculitis is seen primarily

in individuals with a history of herpes simplex infections type I or II. But most notably, it may be a sign of immunosuppression, as is the case with HIV infection.⁷ The expression of herpes folliculitis in HIV infection ranges from simple to necrotizing folliculitis and ulcerative lesions. Molluscum is a pox virus and molluscum contagiosum has been well-documented in similar patient populations (i.e., HIV and AIDS) and in children (see Chapters 129, Herpes Simplex and 130, Molluscum Contagiosum).⁷⁻⁹

- Actinic superficial folliculitis is a sterile form of folliculitis seen predominantly in warm climates or during hot or summer months. Pustules occur primarily on the neck, over the shoulders, upper trunk, and upper arms, usually within 6 to 36 hours after sun exposure.¹⁰
- Eosinophilic folliculitis is associated with HIV infection and can occur as a result of the viral infection itself, in which case the exact mechanism by which this occurs is uncertain (though thought to be autoimmune) (Figure 117-7).^{9,11,12,14} It is associated with diminished CD4 cell counts. Eosinophilic folliculitis generally improves with the initiation of highly active antiretroviral therapy (HAART), but can occur during the restoration of immune function with HAART.¹²

DIAGNOSIS

Often the diagnosis of folliculitis is based on a good history and physical.

CLINICAL FEATURES

Folliculitis has its characteristic presentation as the development of papules or pustules that are thin-walled and surrounded by a margin of erythema or inflammation. Look for a hair at the center of the lesions (Figure 117-2). There is usually an absence of systemic signs and patients, symptoms range from mild discomfort and pruritus to severe pain with extensive involvement.

TYPICAL DISTRIBUTION

Any area of the skin may be affected and often location may be related to the pathogen or cause of folliculitis. The face, scalp, neck, trunk, axillae, extremities, and groin are some of the more common areas affected.

LABORATORY TESTS

Laboratory testing may be unnecessary in simple superficial folliculitis and where the history is clear and quick resolution occurs. Clinical diagnosis of herpes and fungal folliculitis may be difficult and diagnosis may be made based on strong clinical suspicion or as a result of failed antimicrobial therapy. KOH preps can be used to look for tinea versicolor or other fungal organisms. Herpes culture or a quick test for herpes can be used when herpes is suspected.¹ **SOR A**

DIFFERENTIAL DIAGNOSIS

- *Grover disease* is a very pruritic condition of unknown cause that produces reddish papules and slight scale on the backs of middle-aged men. It is also called “transient acantholytic dermatosis” and may resolve spontaneously in a period of years. It resembles folliculitis but the papules are not centered on hair follicles (Figure 117-13).

FIGURE 117-12 A. *Pityrosporum* folliculitis on the chest, shoulders, and arms of a young man; biopsy proven. B. *Pityrosporum* folliculitis on the chest of a young woman. KOH preparation showed *Pityrosporum* looking like ziti and meatballs. (Courtesy of Richard P. Usatine, MD.)

FIGURE 117-13 Grover's disease on the back of a middle-aged man. This is also called “transient acantholytic dermatosis.” It is very pruritic with reddish papules and slight scale. (Courtesy of Richard P. Usatine, MD.)

- *Miliaria* is blockage of the sweat glands that can resemble the small papules of folliculitis. The eccrine sweat glands become blocked so that sweat leaks into the dermis and epidermis. Clinically, skin lesions may range from clear vesicles to pustules. These skin lesions primarily occur in times of increased heat and humidity, and are self-limited (see Chapter 108, Normal Skin Changes).¹
- *Impetigo* is a bacterial infection of the skin that affects the superficial layers of the epidermis as opposed to hair follicles. It is contagious, unlike folliculitis. It has a bullous and nonbullous form, and honey-crusted lesions frequently predominate as opposed to the usual pustules seen in folliculitis (see Chapter 116, Impetigo).^{4,6}
- *Keratosis pilaris* consists of papules that occur as a result of a buildup of keratin in the openings of hair follicles, especially on the lateral upper arms and thighs. It is not an infection but can develop into folliculitis if lesions become infected (see Chapter 145, Atopic Dermatitis).^{1,6}
- *Acne vulgaris* is characterized by the presence of comedones, papules, pustules, and nodules that are a result of follicular hyperproliferation and plugging with excessive sebum. Inflammation occurs when *Propionibacterium acnes* and other inflammatory substances get extruded from the blocked pilosebaceous unit.¹⁵ Although acne on the face is rarely confused with folliculitis, acne on the trunk can resemble folliculitis. To distinguish between them look for facial involvement and comedones seen in acne (see Chapter 112, Acne Vulgaris).

MANAGEMENT

- Management of folliculitis varies by causative agent and underlying pathophysiology.
- Antivirals, antibiotics, and antifungals are used as topical and/or systemic agents. Approaches to nonpharmacologic therapy include patient education on the prevention of chemical and mechanical skin irritation. Glycemic control in diabetic patients may help treat folliculitis.¹⁻³ Good hygiene helps to control symptoms and prevent recurrence.
- With superficial bacterial folliculitis, treatment with topical preparations such as mupirocin (Bactroban) or fusidic acid may be sufficient.¹ **SOR A** Additionally, topical clindamycin may be considered in the mildest cases in which MRSA is involved.¹ **SOR A**
- Deep or extensive bacterial folliculitis warrants oral therapy with first-generation cephalosporins (cephalexin), penicillins (amoxicillin/clavulanate and dicloxacillin), macrolides, or fluoroquinolones.^{1,4,6} **SOR A**
- *Pseudomonas* or “hot tub” folliculitis usually resolves untreated within a week of onset (**Figure 117-1**). For severe cases, treatment with ciprofloxacin provides adequate antipseudomonal coverage.^{1,4} **SOR B** Application of a warm compress to affected areas also provides symptomatic relief.
- *Pityrosporum* folliculitis and/or tinea versicolor can be treated with systemic antifungals, topical azoles, and/or with shampoos containing azoles, selenium, or zinc (**Figure 117-12**) (see Chapter 141, Tinea Versicolor).
- Candidal folliculitis in immunosuppressed persons may be treated with oral itraconazole (see Chapter 136, Candidiasis).¹ **SOR A**
- *Demodex* folliculitis can be treated with ivermectin or topically with 5% permethrin cream.⁴ **SOR B**
- Herpes folliculitis can be treated with acyclovir, valacyclovir, and famciclovir. Regimens may frequently include acyclovir 200 mg 5 times a day for 5 days (see Chapter 129, Herpes Simplex).¹ **SOR A**
- Eosinophilic folliculitis associated with HIV is treated with HAART, topical steroids, antihistamines, itraconazole, metronidazole, oral retinoids, and UV light therapy.¹¹ Topical steroids and NSAIDs and isotretinoin are treatments of choice for HIV-associated eosinophilic folliculitis.⁹⁻¹³ **SOR B** Relief with systemic antihistamines are variable and UV therapy is time-consuming and expensive.^{11,12} **SOR C**

FOLLOW-UP

Most cases of folliculitis are superficial and resolve easily with treatment. Dermatologic and surgical consultation may be required in cases of chronic folliculitis with scarring.

PATIENT EDUCATION

Prevention is most important, and centers on good personal hygiene and proper laundering of clothing. Patients should be encouraged to avoid tight-fitting clothing. Hot tubs should be properly cleaned and the chemicals should be maintained appropriately. Electric razors for shaving can help prevent pseudofolliculitis barbae and should be cleaned regularly with alcohol. Patients with acne keloidalis nuchae should avoid shaving the hair in the involved area.
